1 Introduction

1.1 Overview

In 1995, Honeywell (formerly AlliedSignal, Inc.), the Atlantic Richfield Company (ARCO), and the Georgia Power Company entered into an Administrative Order on Consent (EPA Docket No.: 95-17-C) with the US Environmental Protection Agency (EPA). The AOC requires a Remedial Investigation/Feasibility Study (RI/FS) of the LCP Chemicals Site located in Brunswick, Georgia, to evaluate current conditions and assess response options for the site. The Site is being managed as three Operable Units (OUs). The estuarine setting constitutes OU One (OU1).

This document reports the results of the Remedial Investigation (RI), which describes the nature and spatial distribution of chemicals of concern (COCs) in the estuarine sediments. COCs are derived from the predecessor documents including the Human Health Risk Assessment (HHBRA) document (EPS, 2011) and the Baseline Ecological Risk Assessment (BERA) document (Black and Veatch, 2011), incorporated into this document by reference.

Data have been collected across the LCP marsh over the course of the last 15 years. The size of the database is quite large, with multiple types of data including sediment chemistry, sediment toxicity, pore water and surface water chemistry, multiple biological species tissue concentration, and data pertaining to bioavailability. These data and corresponding interpretations of the data have been reported out in detail in numerous deliverables generally incorporated into this RI Report by reference. Key deliverables previously prepared in support of this RI Report include the HHBRA and BERA documents referenced above, as well as the following deliverables:

- Ecological Assessment Ecological Risk Evaluation of the Salt Marsh and Adjacent Areas of the LCP Superfund Site, Brunswick, Georgia (Sprenger et al., 1997)
- Ecological Risk Assessment of the Marsh Area of the LCP Chemicals Site in Brunswick, Georgia (PTI and CDR, 1998)
- Comprehensive Report of Estuarine Ecological Monitoring at the LCP Chemicals Site, 2000-2003 (MWH, 2005).

All of these data are maintained in a relational database that has been provided to the EPA and Georgia Environmental Protection Division (GAEPD), and the risk assessment reports are included by reference. Therefore it is not necessary to reproduce all of these data herein. This RI Report focuses upon the presentation of sediment chemistry data, as ultimately it is the sediment chemical condition that will form the basis for the scoping of the remedial action.

1

1.2 Purpose

The purpose of this report is to present the current site conditions and summary of risks associated with the LCP salt marsh. It provides the basis for the subsequent FS documents that will present an evaluation of remedial alternatives for the Site.

1.3 Report Organization

The RI Report is organized as follows:

- Section 2 presents background information
- Section 3 provides information on the site setting
- Section 4 presents information related to the removal response action previously performed in the marsh
- Section 5 describes the work performed in support of the RI characterization following the removal action phase

2

- Section 6 presents the nature and extent of contamination
- Section 7 describes chemical transport and fate
- Section 8 is a summary of the HHBRA and BERA
- Section 9 presents the cited references.

2 BACKGROUND

2.1 Location and Surroundings

The former LCP Site property occupies approximately 813 acres immediately northwest of the City of Brunswick, Glynn County, Georgia (Figure 2-1). The property is bordered by a county land disposal facility and a pistol firing range on the north, Ross Road on the east, the Turtle River and associated marshes to the west, and Georgia-Pacific Cellulose to the south. Tidal marshland comprises about 670+ acres of the property. Former manufacturing operations at the LCP Site were located on 133.5 acres of upland area, east of the marsh.

2.2 Past Industrial Activities

ARCO, a successor of the Atlantic Refining Company, operated the Site as a petroleum refinery from 1919 to the early 1930s. At one time, over 100 process and storage tanks were present on Site. The refinery was fueled by coal until 1922, after which oil was used as fuel. The refinery ceased operations by 1935. Concrete tank supports and numerous buildings from this period remain at the Site. Much of the steel was salvaged for scrap in World War II or moved to other locations (GAEPD, 1990).

Georgia Power purchased portions of the Site in 1937, 1942, and 1950. These purchases included two parcels of land and two 750 kilowatt (kW) electric generators from ARCO. Georgia Power subsequently added an additional 4.0 megawatts of electric generation capacity at the Site. Thus, power generation capacity increased at the Site from 1500 kW in 1937 to 5500 kW by 1941. Bunker C oil was used as the fuel source for the power plant (GAEPD, 1990).

The Dixie Paint and Varnish Company operated a paint and varnish manufacturing facility at the Site from 1941 to 1955 on a portion of the Site property south of the Georgia Power parcel. The Dixie Paint and Varnish Company became the Dixie O'Brien Corporation and eventually a wholly owned subsidiary of the O'Brien Corporation (GAEPD, 1990).

In 1955, after acquiring almost all the land constituting what is now known to be the Site, Allied Chemical and Dye Corporation (now Honeywell) established and operated a chlor-alkali facility at the Site, principally for the production of chlorine gas, hydrogen gas, and caustic solution. The plant operated using the mercury cell process, which involves passing a concentrated brine solution between stationary graphite or metal anode and a flowing mercury cathode to produce chlorine gas, sodium hydroxide (caustic) solution, and hydrogen gas. Sodium hypochlorite (bleach) was also produced in a secondary reaction.

LCP purchased the property and chlor-alkali plant in 1979. The chlor-alkali process continued with modification following the purchase. Part of the modification included the production of

hydrochloric acid by reacting chlorine and hydrogen. Manufacturing operations continued until February 1994, when LCP's corporate headquarters implemented an "orderly shutdown" of the plant on February 1, 1994.

2.3 Site Features

Figure 2-2 illustrates the key features of the uplands portion of the Site. The dominant physical feature of the Site property is the 670+ acres of tidal marsh located in the western areas of the Site. The salt marsh is characterized by a flat, heavily vegetated surface (approximate elevation of 2 feet (ft) to 3 ft above mean sea level) dissected by numerous channels and larger creeks under tidal influence from nearby Turtle River.

The upland area to the east of the marshland is characterized by gently sloping terrain from approximately 5 ft above mean sea level along the marsh/upland border to an elevation of approximately 15 ft above mean sea level along Ross Road. This area of the Site is roughly divided in half by the east-west entrance road (B Street). Operations related to the chlor-alkali process were primarily located in the areas south of the entrance road and the area of the boiler house north of B Street, along with smaller isolated waste disposal areas dispersed over the northern half of the Site. The location of the former chlor-alkali plant is covered with a soil cap and is fenced. Refinery operations were present over most of the upland areas. Other than an electrical substation, which has been taken out of service, power generation facilities were north of B Street. The Dixie paint operations were located on the south side of B Street. The southern border of the Site is defined by another rail spur that goes almost to the Turtle River before heading south onto the Georgia-Pacific Cellulose property. B Street is paved to just beyond the north storage warehouse, and is unpaved along the causeway that extends west to Purvis Creek.

4

3 SITE SETTING

3.1 Land Use and Demographics

The LCP property is surrounded primarily by commercial and industrial property. It is bordered by a county land disposal facility and a pistol firing range to the north, a tidal marsh and the Turtle River to the west, the Georgia-Pacific Cellulose facility to the south, and Ross Road on the east, which is defined as an industrial property. The Glynn County Planning Commission Land Use Maps show the area designated as industrial for both present and future use. The "useable" areas of the Site, the marshland from the east bank of Purvis Creek, and the Georgia-Pacific Cellulose site to the south are all zoned "Basic Industrial." The former SIC code for the property is 2812 (Chemicals and Allied Products, Alkalies and Chlorine), which falls within the GAEPD's regulatory definition of non-residential property (391-3-19-.02(2)(i)).

3.2 Physical Setting and Hydrodynamics of the LCP Estuary

3.2.1 General Setting of the LCP Estuary

The approximately 670+ acre LCP marsh is bordered to the west by Turtle River, to the north by Gibson Creek (a tributary to Turtle River) and the Georgia-Pacific Cellulose facility to the south. The prevailing feature of the LCP marsh is Purvis Creek, which divides the marshlands roughly in half - north to south (Figure 3-1A). Purvis Creek traverses most of the LCP estuary entering at the southwest corner of the marsh near the Salt Dock and ending at the northeast upland-marsh border. The tail end of Purvis Creek ends near the former county landfill, but also disperses into a sinuous array of small channels to the north. Purvis Creek has a maximum depth of approximately 11 ft and a maximum width of 500 ft (GAEPD, 1990). The Turtle River is a tidally influenced estuary as are Purvis Creek and other smaller channels, and is considered salt water in the vicinity of Brunswick and the LCP Site. The Turtle River can vary in excess of 9 ft during a tidal cycle.

Numerous smaller tidal channels occur in the LCP estuary. Many of these channels have been named in the course of the BERA including the manmade LCP Ditch (a.k.a. Main Canal), the Eastern Creek, the Western Creek Complex, the Landfill Creek, and the Dillon Duck (Figure 3-1A). The LCP Ditch runs adjacent to the manmade causeway extending from the LCP upland to Purvis Creek. The Eastern Creek feeds into the LCP Ditch at approximately its midpoint and drains the eastern half of the LCP marsh south of the causeway road (Figure 3-1A). Approximately 500 ft downstream from where the LCP Ditch enters Purvis Creek is the mouth of the Western Creek Complex. The Western Creek Complex is comprised of three principal channels and drains the western half of the LCP marsh below the causeway. The Landfill Creek

borders the old county landfill at the northern portion of the LCP marsh, and is proximate to the Dillon Duck feature. The physical breakup of the LCP marsh by these physical features lead to the development of "domains" in the BERA, or areas of similar physical setting (and contaminant characteristic), shown also on Figure 3-1A.

3.2.2 Spartina Salt Marshes

Spartina-dominated salt marshes, such as are common in the Southeastern United States and the LCP Site, are broad, nearly level meadows dominated by a plant community with differing tolerances to tidal inundation and the resultant fluctuations in dissolved oxygen availability as well as surface water and soil salinity. Salt marshes develop on low energy coastlines where tide and wave forces are limited and sedimentation allows for the development of salt tolerant plant communities. The development of anchored plant communities initiates a feedback loop for marsh propagation because rooted vegetation tends to dampen flow velocities, resulting in the enhanced potential for sedimentation in the vicinity of extant vegetation. In terms of landscape geometry, salt marshes can be defined by a bimodal distribution of elevations, in which any particular location is characterized as either marsh surface or tidal mud (or sand) flat (Fagherazzi et al. 2006). Areas of intermediate elevation tend to become either destabilized through the action of shallow water waves or stabilized through vegetative growth, such that marsh geometry is more commonly defined by flat planes (i.e., the marsh surface and tidal flat) and right angles (i.e., the marsh edge), than by sloped surfaces.

In *Spartina*-dominated marshes, cordgrass meadows are interspersed with tidal creeks many of which drain to expose mudflats at low tide. The scale and orientation of tidal creeks varies widely, with the result that, although salt marshes are described by a banded succession of plant species from the low marsh (dominated by the cordgrass *Spartina alternifola*) to the intermediate marsh (dominated by the cordgrass *Spartina patens*) to the high marsh (dominated by the needlerush *Juncus sp.* and the bulrush *Scirpus sp.*), this spatial distribution of plant types is also strongly influenced by proximity to tidal creeks, with low marsh vegetation commonly dominating the plant community on the creek banks. The schematic shown below illustrates the physiographic features typical of salt marshes in Georgia. The interaction of biological and physical process within a salt marsh thus results in the development of low marsh habitat and resultant creek edges/boundaries that interweave throughout the marsh.

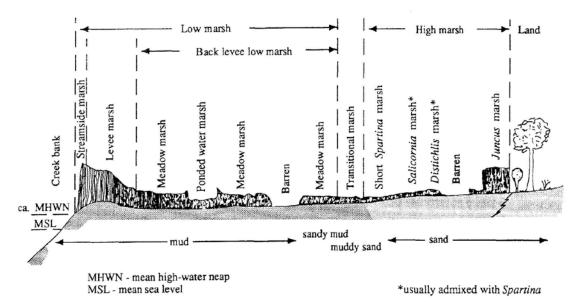

Fig. 2.2. Cross-sectional view of the sedimentary development of an intertidal salt marsh, based on the model of Frey and Basan (1985).

Although salt marshes may receive sediment from the shoreward direction, the dominant external source of sediment to salt marshes is the coastal ocean. Salt marshes are "net depositional" coastal features, and thus act as "sediment sinks," particularly when viewed on a large scale and over the long term. Studies of contaminant storage in salt marshes, for example, commonly conclude that marsh cores serve as reliable chronologies of contaminant inputs (Cundy et al., 1997; Fox et al., 1999). This overall assessment of sediment (and chemical) retention in salt marshes is scale-dependent, however, and marsh accretion rates (vertically and laterally) are significantly influenced by factors including: the age of the marsh; tidal range; the magnitude and consistency of sediment supply from the coastal ocean; the extent to which high energy weather events are dominated by onshore versus offshore winds; and human behavior (Van der Wal and Pye, 2004; Temmerman et al., 2004; Draut et al., 2005). Moreover, localized erosion, such as along the edges of tidal creeks, can redistribute sediment mass within an estuary or embayment (Feagin et al., 2009).

3.2.3 Historical Alteration of the Tidal Channels

Historical developments altered marsh drainage patterns at the Site. Portions of the marsh have been isolated from their original stream drainages to Purvis Creek and the Turtle River due to construction of causeways that lead to a tanker dock on the Turtle River and to the area now occupied by the salt dock (Figure 3-1A). Although these activities occurred prior to available aerial photography over the area, ponded water in isolated drainages was visible in 1942, indicating continuing adjustment of the drainage system to the causeway construction.

Glynn County began landfilling operations around 1953 just north of the Site along the edge of the marsh. By 1968, this landfill had isolated approximately 20 acres of marsh just north of the tanker dock causeway from its drainage to the north (Figure 3-1A). Over the last few decades,

this area has adjusted to drain directly westward. There appears to be no other county infrastructure present in the area in 1965. The 1968 aerial shows some buildings were constructed on the county property. By 1970 the landfill has expanded along its perimeter (to approximately its current configuration) and portions of a bordering tidal channel appear to have been filled. The pistol firing range first appears in the 1973 aerial.

The most recent alteration of marsh drainage patterns occurred during the 1998-1999 marsh removal action. During the marsh removal action a temporary piling wall was erected in the marsh to isolate the approximately 13 acres of removal area. As a result of the piling wall a portion of Eastern Creek adjusted its route at the southern end of the removal action area. In addition, tidal channels or tributaries to Eastern Creek extending landward were truncated. These features and the footprint of the marsh removal area are visible in more recent aerial photographs.

3.2.4 Estuarine Hydrodynamics

The Turtle River and its associated tidal creeks and tributaries are not rivers and creeks in the traditional sense; rather, they are tidally influenced systems. Studies of estuarine hydrodynamics of the Duplin River, a tidal channel of similar character and setting to the Turtle River, provide insight into the hydrology and characteristics within the LCP marsh and broader area of the Turtle River (Ragotzkie and Bryson, 1955; Ragotzkie and Pomeroy, 1957). The hydrodynamics within the Turtle River and its tributaries is governed by *semi*-diurnal tidal forces. Three tidal zones (termed "prisms") occur in these types of estuarine river systems, as well as within smaller tidal channels:

- Headwater Zone (upper reaches) water rises from the channel onto the marsh flats on the flood tide, and spills back into the channel on the ebb.
- Middle Zone water oscillates (with little mixing) back and forth with tides.
- Lower Zone (mouth) water leaves the river channel on each ebb tide and is replaced with "new" water on the subsequent flood tide (this phenomenon is termed "excursion").

During the flood tide, water feeds in from St. Simons Sound and into the Turtle River and into smaller tidal channel reaches. As the water level rises, it spills over the channel banks and across the broad vegetated marsh flats. This water spreads to the point of the "tidal node" where it meets flood tide waters from an adjacent channel. Waters then recede from the tidal node back into the channels during the ebb tide cycle. Ebb tides have slightly higher water velocity than the flood tide whereas the flood tide duration is slightly longer compared to ebb. A generalized conceptual model of the marsh hydrodynamics is central to the discussion and understanding of observed COC distributions presented later in this document.

3.3 Physical and General Chemical Properties of the Marsh Flats and Tidal Channel Sediments

3.3.1 Marsh Sediment Classification

According to the Soil Conservation Survey of Glynn County, the marsh areas are underlain by soils of the Bohicket-Capers association (BO or Bohicket) (Rigdon and Green, 1980). Rigdon and Green (1980) describe Bohicket soils as follows:

[The BO soils]...consist of very poorly drained soils in a regular and repeating pattern. The landscape consists of level tidal marshes that border the Atlantic Ocean and extend a few miles inland along creeks and rivers...These soils formed in silty and clayey marine sediment.

Bohicket soils make up 80 percent of the unit. Typically, the surface layer is dark gray silty clay loam about 8 inches thick. The substratum is dark greenish-gray silty clay and clay to a depth of 65 inches or more. There are many fibrous grass roots throughout. Bohicket soils have very slow permeability...The sulfur content is 2 to 3 percent and a strong hydrogen sulfide odor is noticeable when the soil is disturbed. Bohicket soils are flooded by seawater twice each day.

The Bohicket soils in the LCP Estuary may not be as generally characterized by Ridgon and Green (1980). For example, though site-specific sediment data from the 2000 and 2006 ecological sampling field events do not include total sulfur data, sulfide content ranged from 0.2 milligrams per kilogram (mg/kg) to 1,300 mg/kg, with a mean of 240.9 mg/kg (n = 102), which is lower than reported by Rigdon and Green (1980).

3.3.2 Physical Properties of Marsh and Channel Sediments

One of the "supplemental studies" conducted as part of the 2002 ecological monitoring event involved the collection of sediment samples for characterization of physical/chemical properties. Table 3-1 summarizes the results of the geochemical properties testing of these marsh sediment samples, and these sampling locations are indicated on Figure 3-1B. The soil pH was neutral to slightly alkaline and ranged from 7.2 to 8.0 standard units. Total organic carbon (TOC) levels were high and ranged from 1,900 to 130,000 mg/kg on a dry weight basis (0.19% to 13%), with most samples in the 3% to 6% range. This reflects a typical wetlands environment with relatively slow decomposition of organic matter (OM) under submerged and partially anaerobic conditions, which leads to an accumulation of organic carbon in surface sediment. The cation exchange capacity (CEC) was fairly high, and ranged from 22 to 41 centimoles of charge per kilogram (cmol_c/kg). It was much higher than the anion exchange capacity (AEC), as would be expected under mildly alkaline soil conditions. These CEC concentrations are consistent with typical ranges observed in soils with high OM content and neutral to alkaline pH conditions such

as Mollisols and Histosols (Sumner, 2000). Iron oxide levels ranged from non-detect to 8,400 mg/kg (0.84%), with most samples being in the 0.3% to 0.4% range.

The channel sediments consisted mostly of clayey silt with very high moisture contents. Results of the particle size analysis for samples are summarized in Table 3-2, the sampling locations are shown on Figure 3-1B. The texture classification of these samples ranged from sandy clay loam (two samples) to sandy clay (two samples) to clay (four samples) according to the United States Department of Agriculture (USDA) soil texture triangle. The high CEC of these samples is a reflection of the high organic carbon and clay content in these sediments.

Mineralogical testing results are summarized in Table 3-3, the sampling locations are shown on Figure 3-1B. Mineralogical analysis was performed to identify major reactive soil components that may be controlling mercury and lead solubility. The mineralogical analysis identified quartz, pyrite, halite, clay (i.e., unspecified clay minerals), non-crystalline inorganics, and organics. The predominant minerals, by weight, were non-crystalline inorganics, which includes amorphous iron oxides and other precipitates, and quartz. A significant percentage by weight (generally 10 - 20%) of the sediment makeup was identified as organic matter (OM).

3.3.3 Generalized Marsh Site Model

A cross-sectional view of the LCP marsh, including the transition from the upland is provided in Figure 3-2. The dominant features of the cross section, from the surface down include a dense root mat, a low permeability marsh clay $(1.3 \times 10^{-7} \text{ to } 1.8 \times 10^{-8} \text{ cm/s})$ (GeoSyntec, 1997), the Satilla Sand aquifer, and at the base the cemented sandstone layer.

The dense root mat zone exhibits high organic carbon content (5,300 to 80,000 mg/kg) and supports an active layer of *Spartina* grass. Below the root mat zone, the marsh clay extends several feet in depth (on average about 7-8 ft). Below the marsh clay is the Satilla Sand aquifer, which is composed primarily of fine to medium grained sand. Beneath the Satilla Sands is the semi-confining cemented sandstone layer.

3.3.4 Marsh Stratigraphy

Two episodes of investigation into the thickness and continuity of the marsh surface clay have been completed (see "MC" and "MGB" boring locations on Figure 3-3). The first investigation (MC borings) consisted of 24 hand auger borings used to evaluate the thickness and nature of the marsh clay near the marsh edge. The second investigation (MGB borings) consisted of 14 hand auger borings in the eventual marsh flats removal area. These studies were supplemented with boring logs from marsh monitoring well installations and more recent "peeper" installations in the marsh to depict the thickness of the marsh clay that overlies the surficial aquifer. Figure 3-4 shows the clay thickness measured at these numerous locations throughout the marsh. At all but one near-shore location, the marsh clay thickness generally ranged from 5 to 10.5 ft; there was one location where the marsh clay was reported to be 20 ft thick. The one location that had less than 5 ft of clay was located at the marsh shore and had a thickness of 2.5 ft.

Drawing 1 shows a number of stratigraphic cross sections across the LCP marsh along the near-shore area. The stratigraphy is characterized in a downward sequence of mixed root mat with sediment, a "muck" or very soft clay layer, a layer of firm clay transitioning to sandy clay/clayey sand and then to the Satilla Sand aquifer (surficial aquifer at the Site).

These measurements were used with the infrared (IR) imaging to characterize the contiguousness of the marsh clay layer in the context of the groundwater conceptual site model (see Section 7.3). Though the stratigraphic profile is generally consistent across the area of investigation, the IR imaging identified localized discontinuities in the marsh surface temperature (Stockton Infrared Thermographic Services, 2009). Notably, the IR imagery was unable to penetrate submerged rivers and creeks. Thus, additional discontinuities may exist in certain larger channels (creeks) that meander through the estuary marsh and that were submerged during the IR imaging process, but these areas also are net depositional and thus are expected to be consistent with the marsh clay layer.

The distributions of total organic carbon (TOC) and fine particles throughout the site are shown in Figures 3-5 and 3-6, respectively. In undisturbed areas, the average TOC levels were generally above 2.5%, except at a few isolated locations (Figure 3-5); lower levels of 1% to 2.5% and < 1% TOC occurred in the remediated areas of Domain 1, which is attributed to the borrow material used to backfill the marsh after remediation. A consistent distribution of average percent fine particulates also was observed; most locations in undisturbed areas had >75% fines, and all had >50% fines, consistent with mud flat channels. Less than 25-50% fines occurred in the remediated areas of Domain 1, which also was attributed to the borrow material used to backfill the marsh.

4 SITE INVESTIGATIONS PERFORMED IN SUPPORT OF THE 1998-1999 MARSH REMOVAL ACTION

4.1 Pre-removal Marsh Characterization Events

4.1.1 Overview

Multiple parties performed investigations in the LCP marsh to determine the scope of a removal action that was performed in 1998-1999. The EPA conducted a three-phase sample investigation during 1995 in the marsh flats and the tidal channels at the direction of the On-Scene Coordinator (OSC) for use in assessing the need for and scope of removal action in the marsh. GeoSyntec Consultants (GeoSyntec) performed limited sampling in the marsh over the period of 1995-1997, and PTI Environmental Services (PTI) performed additional sampling in 1996. The National Oceanic and Atmospheric Administration (NOAA) also performed a monitoring study in the marsh and tidal channels in 1997. A summary of these events is provided below and figures are provided for each major sampling event.

4.1.2 EPA (1995)

The EPA conducted three sampling events in 1995. A major part of the EPA's sampling program was conducted along a grid, established immediately west of the Former Facility Disposal Area (FFDA) (a former land disposal site) and south of the B-Street causeway (Figure 4-1). Additional sampling in the outer reaches of the LCP estuary (west of Purvis Creek) was also performed. Figure 4-1 shows the separate phases of these sampling events. In all, over 200 separate locations were sampled by EPA in 1995. These sampling events included other media samples such as biota and toxicological test samples in addition to sediment chemistry.

4.1.3 PTI (1996)

In 1996 PTI completed a sediment sampling event consistent with the event completed by the EPA in 1995, involving sampling at well over 100 separate locations across the LCP marsh and adjacent area. This sampling event was completed in part to confirm the 1995 EPA results which lacked accurate position coordinates due to global position limitations during this period. Sediment sampling was focused in the in the area between the marsh-upland border and Eastern Creek below the B-Street causeway (Figure 4-2). Additional sampling in the outer reaches of the LCP estuary (west of Purvis Creek) was also performed but at a lower sampling density. This

sampling event included other media samples such as biota and toxicological test samples in addition to sediment chemistry.

4.1.4 GeoSyntec Consultants (1995-1997)

GeoSyntec performed more limited scopes of sampling in support of the other studies by EPA and PTI, prior to the removal action. GeoSyntec conducted two sampling events in 1995. The first event, conducted in June 1995, involved sediment sampling at 17 locations in the marsh along the perimeter of the FFDA and two additional locations in the same vicinity (this event is labeled in the database as "1995-sed"). Later in September 1995, in support of the uplands removal action, GeoSyntec sampled near-shore sediment at three locations immediately west of each of two former API separators (one north of B-Street and one south of B-Street). This event is labeled in the database as "GeoSyntec Removal Action Sampling". In 1996, three locations were sampled in the Dillon Duck area at the north end of the Site and two locations were sampled west of the FFDA in support of a removal action treatability test. A more comprehensive sampling was performed in 1997 involving sediment collection from 22 locations across the entire LCP marsh (identified as the "1997-sed" event). These sampling events are depicted on Figure 4-3.

4.1.5 NOAA (1997)

In 1997, NOAA performed a sampling event involving eight locations across the LCP marsh (Figure 4-4). The study focused on sediment sampling in the LCP estuary south of the B-Street causeway and east of Purvis Creek. Biota and sediment samples were also collected for laboratory toxicity testing.

4.2 Sampling in Support of the 1998-1999 Marsh Removal Response Action

In 1998-1999, approximately 13 acres of marsh flats (nearest the sources of historical facility discharges) were excavated, backfilled to restore grade, and re-vegetated with native marsh grasses. Dredging was also performed along a portion of the Eastern Creek and in select portions of the LCP Ditch (2,650 linear feet). Figure 4-5 shows the Marsh Removal Area and extent of dredging in the LCP Ditch and Eastern Creek. Details of the removal response activities performed at the marsh and tidal channels are documented in the "Close-Out Report, Marsh Area" submitted to the EPA project OSC in October 1999 (GeoSyntec, 1999). This Close-Out Report includes the following information: (i) characterization and delineation sampling and analytical results, (ii) waste removal activities; (iii) confirmation sampling and analytical results; (iv) removal record drawings; and (v) marsh flats restoration activities.

Sampling support for the marsh removal action included several separate events spanning the timeframe from 1997 (pre-removal planning) through 1999 (post removal). These events were

performed by GeoSyntec Consultants and included the following events (refer to Figure 4-6 for locations):

- Fall 1997 LCP Ditch Sampling: Sample ID identified by Julian date; locations were focused in the western half of the LCP Ditch along the bank and channel with 112 locations sampled in all; all samples were surface sediment (0-1ft).
- Marsh Exploration: 1997; 14 core sample locations with Sample ID "MGB-" at sampling depths up to 7.5ft; exploration also included two exploratory test pits with Sample ID "MTD-" with sampling down to 2ft; all locations were west of the FFDA.
- Eastern Marsh Delineation: 1998; involved collection of 14 surface (0-1ft) and shallow subsurface (1-2ft) sediment samples along eastern portion of marsh, with Sample ID "MED-".
- Marsh Delineation: 1998; involved collection of 52 surface (0-1ft) and shallow subsurface (1-2 and 2-2.2ft) sediment samples west of the FFDA; identified with Sample ID "MS-".
- Channel Sediment Characterization: 1998; shallow sediment core samples (depths to about 2ft) at 14 locations within the LCP Ditch (east of its confluence with Eastern Creek), identified with Sample ID "CTS".
- Channel Sediment Confirmational: 1998-99; program involved sediment sampling along transects every 50 linear feet of the LCP Ditch channel (east of its confluence with Eastern Creek) and along Eastern Creek (one in channel center and one on each bank); sediment cores were taken to depths of up to about 4ft, all with Sample ID "CSC-".
- Marsh Confirmational: 1998-99; sampling was performed across the 13 acres of remediated marsh flats immediately below the backfill soil, from 14 locations all with Sample ID "MSC-"; separate event also involved re-sampling at three locations reported in the 1995 EPA grid program (K-18; I-27; G30; J-31).

4.3 COC Distributions Established From the Removal Action Sampling Support

4.3.1 Overview

The compilation of pre-removal action and removal action support sampling events provides a comprehensive data set for the understanding of the original COC distributions in the marsh. Data selected for the mapping of the surficial sediment condition were queried by the use of the "D1" field (i.e., top of the sampling interval) in the database – in this case a D1 of 0 was chosen to represent the surficial condition depicting the lateral distribution of COCs (Section 4.3.2 below). A discussion of the vertical distribution of COCs follows in Section 4.3.3.

4.3.2 Lateral Distribution (Surficial Sediment)

4.3.2.1 Mercury (Figure 4-7A)

The pre-removal condition for mercury in the surficial marsh sediment is depicted in Figure 4-7A. Concentrations in excess of 100 milligrams per kilogram (mg/kg) were common in sediments bordering the FFDA, also in the same area where process sewer lines once discharged process wastewater to the estuary. Mercury concentration decreases along a fairly sharp gradient westward out along the marsh flats. For example, the concentration drops to a condition of about 10 mg/kg along a lateral distance of between 300 ft to 500 ft from the upland shoreline. The LCP Ditch most proximate to the uplands also exhibited mercury concentration in sediment in excess of 100 mg/kg, also following a general concentration gradient of decreasing concentration further along the LCP Ditch. Another area of more elevated concentration is exhibited in the Eastern Creek.

As previously mentioned, the scope of the marsh removal action was developed on the basis of COC mass removal. The outer boundary of the 13-acre region of marsh flats removed/restored represented a line estimated at 25 mg/kg mercury (see gray shaded area on Figure 4-7A).

4.3.2.2 Aroclor-1268 (Figure 4-7B)

The Aroclor-1268 pre-removal condition was quite similar to mercury (as described above), with perhaps generally higher concentrations in the tidal channels and somewhat lower concentrations in marsh flats compared to mercury at the same sampling locations.

4.3.2.3 Lead (Figure 4-7C)

The lateral distribution of lead in the surficial sediments was similar to mercury and Aroclor-1268 in the areas described above, west of the FFDA and process sewer discharge locations that discharged process wastewater. Here the near-shore sediments were generally in the range of 250 mg/kg to 500 mg/kg, diminishing to a range of around 10 mg/kg to 50 mg/kg a relatively short distance westward with this condition then persisting throughout most all of the rest of the LCP marsh. A second general area of elevated lead concentration occurs in the Dillon Duck wetland area and adjacent tidal creek bordering the northern shoreline of the LCP Site and the County landfill and firearms firing range further to the north.

4.3.2.4 PAHs (Figure 4-7D)

Figure 4-7D shows the lateral distribution of summed polycyclic aromatic hydrocarbons (PAHs) (taking the sum of actual detected results; non-detect results were not factored into the summation in order to maintain consistency of the summation across the multiple sampling events with varying detection limits). Lesser locations were sampled for PAHs, and the detected concentrations were much lower than the other COCs with most locations under 1 mg/kg to under 0.5 mg/kg. The more elevated concentrations are once again located in near-shore areas both along the northern and southern shoreline areas and tidal channels.

4.3.3 Vertical Distribution of COCs in Sediment

The vertical distribution of mercury, Aroclor-1268, lead, and total PAHs in the upper few feet of marsh sediment was evaluated by EPA and PTI in the 1995 and 1996 sampling investigations, respectively. Multiple samples were collected and tested for these COCs at discrete depths at numerous locations:

- 20 locations were sampled in the area of greatest contamination of the marsh surface (Domain 1)
- 2 locations were sampled in the areas of the Western Creek Complex (Domain 2)
- 6 locations were sampled in the northeast portion of the marsh (Domain 3)
- 4 locations were sampled in Purvis Creek
- 7 locations were sampled in LCP Ditch

Appendix A1 provides graphical profiles of the depth-interval sampling results for the COCs.

Thirty nine cores were collected to different depths below the sediment surface to profile chemical concentrations:

- 16 cores were collected to a depth of 0.8 ft or less (five in Domain 1, two in Domain 2, four in Domain 3, three in Purvis Creek, and two in LCP Ditch)
- 20 cores were collected to a depth of 1 ft or 1.2 ft (15 in Domain 1, one in Purvis Creek¹, and four in LCP Ditch)
- Three cores were collected at varying depths deeper than 1.2 ft (two in Domain 3 and one in LCP Ditch)

4.3.3.1 Observed Aroclor-1268 and Mercury Vertical Distributions

Among the 16 cores collected to a depth of 0.8 ft or less, non-detect levels were approached within the upper 0.8 ft sample interval in eight cores. The remaining shorter profiles could not be used to identify the depth of contamination at these locations because the data did not extend beyond 0.8 ft, where declines in mercury and Aroclor-1268 concentrations were observed in the deeper cores.

Among the 20 cores that were collected to a depth of 1 ft or 1.2 ft, 17 cores were characterized by higher mercury and Aroclor-1268 concentrations that were confined to the upper 0.8 ft; while concentrations at depths between 0.8 ft and 1.2 ft, approached non-detect levels.

Among the three cores collected at deeper depths, concentrations were low or approaching non-detect at 1.6 ft or deeper. The LCP Ditch core showed decreasing concentrations that were less than 20 mg/kg mercury and less than 2 mg/kg Aroclor-1268 at 1.6 ft depth. The two Domain 3 locations were characterized by low chemical concentrations at all depths (less than 6 mg/kg mercury and less than 2 mg/kg Aroclor-1268).

-

¹ The Purvis Creek core PC110 was sampled to 1 ft for Aroclor-1268 and PAHs and to 2.25 ft for lead and mercury.

4.3.3.2 Observed PAH and Lead Vertical Distributions

Total PAH and lead were not collected at all 39 locations, but all domains were represented. All of the Domain 1 cores were collected from the removal area (pre-removal) and had lead concentrations above 40 mg/kg. In the other locations, eight of the ten cores analyzed for lead were characterized by sediment concentrations below 40 mg/kg at all depths, and eight of the ten cores analyzed for PAHs were characterized by sediment concentrations below 4 mg/kg. Sample locations in close proximity did not necessarily show similar trends (for example, HA-01 and HA-04 were less than 25 feet apart yet the total PAH concentrations at the 4-6 ft depth interval was non-detect to 2 mg/kg in HA-01 and at the 5-ft depth interval the concentration was 83 mg/kg in HA-04).

4.3.3.3 Domain 1 Vertical Distributions Associated with the Removal Action

Additional depth profiling was performed as part of the marsh exploration sampling in 1997. During this investigation, sampling was performed to depths of up to 8 ft in the Domain 1 Removal Area. Depth-interval maps of mercury, Aroclor-1268, and lead in the sediments are provided in Appendix A2. Beyond depths of 1 ft, Aroclor-1268 concentrations were typically non-detect, and mercury concentrations were below 10 mg/kg, except for core locations directly adjacent to the LCP Ditch and the FFDA. Lead vertical profiles were confined to a depth of 3 ft, but below depths of 1 ft lead concentrations were less than 50 mg/kg.

4.3.4 Distribution of Concentrations in Sediment Over Time

A total of 76 locations within the Site were sampled over multiple years and analyzed for mercury or Aroclor-1268. Depending on the location, samples were collected 2 to 7 times between 2000 and 2007. Figures 4-8A and 4-8B show temporal trends by creek or domain for mercury and Aroclor-1268, respectively, for locations with at least four time points. All data (including data for locations with two or three time points) are included in the project database and are reported in Tables 4-1a and 4-1b for mercury and Aroclor-1268, respectively.

In general, there is not a consistent trend in surface sediment contamination levels over time for either chemical, across the site. The r^2 the linear regressions representing each data point over time are shown in Figures 4-1a and 4-1b. Overall, r^2 values average 0.34 ± 0.32 for mercury and 0.30 ± 0.31 for Aroclor-1268; median values were 0.24 and 0.19, respectively. Lower r^2 values were obtained when samples were binned across the site. For example, when averaging all seven samples collected at each time point for samples collected at seven time points, the r^2 values for mercury and Aroclor 1268 were 0.15 and 0.05, respectively. Though it may be tempting to think that there may be some trends when r^2 values were above 0.7 for some locations, such trends are unreliable when considering that adjacent locations within the same area show much greater variability and no reliable trends at all.

The following reasons may explain the lack of downward trends:

- 1. It is often difficult to collect samples from precisely the same location during multiple sample events; thus some of the observed variability may be due to localized spatial heterogeneity in sediment concentrations.
- 2. Whereas the site is net depositional, deposition rates are low. Thus there has not been substantial historical burial of surface sediment deposits over time, making it difficult to discern historical time trends.
- 3. The relatively high concentrations in such locations as the LCP Ditch and Eastern Creek areas may have contributed to localized mixing and localized sediment redistribution, thus confounding the time trend results.

5 WORK PERFORMED IN DIRECT SUPPORT OF THE RI SITE CHARACTERIZATION

5.1 Surveys

5.1.1 Property Boundary Survey

Pruitt and Purcell, P.C. surveyed the LCP property boundary in 1989. As second boundary survey (with full title search) was completed by their successor company, EMC Engineering Inc. in 2008. The most recent survey was completed by Shupe Surveying Company, P.C. in January 2009. The property boundary is provided in Figure 5-1.

5.1.2 Ground Surveys

Pruitt & Purcell, P.C, provided ground survey control throughout removal actions. Ground surveys included: (i) establishing reference grids for removal excavation; (ii) establishing lateral coordinate positions of sampling locations; and (iii) survey support for site grading. Subsequent investigative sample locations were recorded with a field Global Positioning System (GPS).

5.2 Post-removal Baseline Site Characterization and Subsequent Annual Monitoring with Supplemental Studies

EPA requested that a baseline sampling event be performed following the marsh removal action, in support of the BERA. This baseline event was performed in 2000 by CDR Environmental. Beginning in the year 2002 and extending through 2007, annual monitoring was performed in addition to numerous "supplemental studies." The compilation of all of these data, from 2000 to 2007, represents more than 800 separate locations sampled across the LCP marsh flats, channels, and locations beyond, in addition to the hundreds of separate sample locations prior to 2000. Like the previous ecological studies performed by EPA in 1995 and PTI in 1996, the CDR Environmental studies were multi-media in scope involving sediment chemistry, surface water (and at times sediment pore water) chemistry, biota tissue, and various forms of toxicity testing. The following data presentation focuses upon the sediment chemistry.

• 2000 Baseline Event (Figure 5-2A): sediment Sample ID "C-" and "M-" depicting separate locations for creek (channel) and marsh (flats), respectively; 46 locations often

- with paired C and M samples; also several locations of the EPA 1995 sampling grid (outside the removal action zone) were resampled.
- 2002 Eco Event (Figure 5-2B): many of same "C-" and "M-" sediment locations from the 2000 baseline sampling were sampled again; event also included multiple sediment sampling locations labeled as "LYS-" at each of the five groundwater seepage areas along the southern uplands-marsh border area; event also included additional locations of sediment re-sampling of some of the 1995 EPA grid locations; some additional locations also sampled in the marsh including the "A-D" channel west of Purvis Creek; work also involved sequential extraction procedure (SEP) analysis of sediment bioavailability (described in latter section of this RI Report).
- 2003 Eco Event (Figure 5-2C): most of same sediment locations from the 2002 monitoring event were again sampled; major supplemental study involving 25 sediment samples each along the LCP Ditch (Sample ID "SM-"), Eastern Creek (Sample ID "SE-"), and remediated marsh flats (Sample ID "SD-"); work also involved SEP analysis of sediment bioavailability (described in latter section of this RI Report).
- 2004 Eco Event (Figure 5-2D): most of sediment sample locations from 2002 event were involved in the monitoring element of this event; major supplemental studies involving extensive sediment sampling in the LCP marsh west of Purvis Creek, and also in a marsh flats area west of the LCP marsh along Blythe Island (across the Turtle River) in area known as Morrison Slough; 188 locations in all were sampled for sediment.
- 2005 Eco Event (Figure 5-2E): most of sample locations from previous monitoring programs were again sampled for the monitoring element of this event; also included major supplemental studies involving extensive sediment sampling within Purvis Creek and additional areas to the west of Purvis Creek; some of the same locations sampled in 2004 in Morrison Slough were sampled again in 2005.
- 2006 Eco Event (Figure 5-2F): monitoring element of program employed concept of "sentinel" monitoring and involved a subset of past monitoring stations; major supplemental studies in support of an apparent effects threshold (AET) evaluation involving sediment sampling from 50 separate locations each along the three tidal tributaries of primary interest (LCP Ditch; Eastern Creek; western segment of Western Creek Complex); the same locations sampled in 2005 in Morrison Slough were sampled again in 2006.
- 2007 Eco Event (Figure 5-2G): this was a more basic monitoring-only sampling scope employing the same sentinel stations as from the 2006 ecological sampling event.

5.3 Project Database and Geographic Information System

All of the environmental data records generated in the course of the pre-removal as well as post-removal site characterizations are maintained by EPS in a Microsoft® Access project database. The database contains numerous fields to account for specialized attributes of various samples or sample groups. For example, a field entitled "Removed" is used to identify whether a sample

location was remediated during the marsh cleanup of 1998-1999 (and hence the data point is no longer valid for a current representation of that location condition). Another field is entitled "Post Ex" to identify those samples that represent either a sidewall composite or base of excavation composite conformational sample. Other fields are used for depth interval ("D1" and "D2") and other important attributes. Map-based information is maintained in a Geographic Information System (GIS).

This RI Report focuses upon the presentation and discussion of sediment matrix sample results as this is the information pertinent to the development of the FS alternatives. Appendix B provides the results of the query of the master database for sediment matrix data records for the COCs, used in the development of the RI Report figures presented herein. The project database contains other matrix sample results in addition to sediment (e.g., various biota; surface water; and toxicological testing results) that are presented in the BERA.

6 NATURE AND EXTENT OF RESIDUAL CONTAMINATION (POST-REMOVAL)

6.1 Data Selection for the COC Mapping of the Post-removal Action Marsh Sediment Condition

This section presents the post-removal Site characterization sampling results. Sample locations that were sampled on more than one event (i.e., locations of monitoring) were queried for the highest detected COC concentration result. Samples collected as field duplicates for quality control are flagged as such in the database and these record types were not included in the query, in order to avoid duplicate results for the same sample location.

6.2 Nature of Contamination

The BERA evaluated all of the data records (sediment, biota, toxicity) generated in the course of the post-removal action Site characterization and monitoring events, and likewise the HHBRA evaluated the full data set pertinent to human health issues. Both of these assessments screened all of the analytical records and evaluated their contribution to the computed risks. These assessments lead to the identification of COCs identified in Section 7 of the BERA which include the following:

- Mercury
- Aroclor-1268
- Lead
- Total PAHs

6.3 Concentration Distribution of Post-removal Action COCs in Marsh Sediment

The site has been delineated to levels consistent with the risk estimates, and to satisfy the requirements of the FS to establish a basis for action at the site. The chemical distributions of each of the four COCs are presented in the following subsections.

6.3.1 Mercury (Figure 6-1A)

The distribution of mercury in the surficial sediments sampled in the post-removal action studies follows the same general patterns identified in the pre-removal studies described in Section 4.3.2.

The highest mercury concentrations, typically in the range of between 10 mg/kg to 100 mg/kg, are found in the Eastern Creek, most notably in the southern half of the channel where the dredging was limited (owing to the more restricted channel width and meandering nature of the channel) and further south beyond the limits of where dredging occurred in the removal action. Elevated mercury concentrations also occur in the LCP Ditch, most notably in the region where the Eastern Creek joins this feature, with concentrations typically in the range of 5 mg/kg to 25 mg/kg. A third area of note is the western segment of the Western Creek Complex, where mercury concentrations are generally highest in the "headwater" portion of this channel and in the range of around 5 mg/kg to 25 mg/kg. In the marsh flats and tidal channels beyond these regions, including Purvis Creek, sediment mercury levels are typically at concentrations of less than 2-5 mg/kg, and lower yet in the marsh west of the tidal node central within Domain 4.

Some of the sampling events included locations in the area known as Morrison Slough, a marsh flats expanse on the west bank of the Turtle River outside of the LCP Site (along Blythe Island) and across from Purvis Creek. As shown in Figure 6-1A, here the mercury concentrations in the surface sediments were all under 0.5 mg/kg.

Methylmercury (MeHg) was measured at over 150 sediment sampling locations throughout the site (Figure 6-1B). The MeHg in sediment ranged from below detection to 0.11 mg/kg, with a mean concentration of 0.008 mg/kg (n=157). Processes affecting mercury methylation are discussed in Section 7.4.

6.3.2 Aroclor-1268 (Figure 6-1C)

Sediment Aroclor-1268 concentrations exhibit a spatial pattern generally consistent with that of mercury, with the highest sediment concentrations observed in the LCP Ditch and Eastern Creek. The Aroclor-1268 concentrations are noticeably higher compared to mercury at these locations, with many more sample locations in the range of 25 mg/kg to 100 mg/kg or higher. Aroclor-1268 concentrations also tend to be a bit higher compared with mercury in Purvis Creek, in particular in the central portion of Purvis Creek where Aroclor-1268 is in the range of 5 mg/kg to about 10 mg/kg. Similar to mercury, the Aroclor-1268 concentrations are lower west of the tidal node.

Aroclor-1268 concentrations in sediment within the Morrison Slough marsh were all below 0.5 mg/kg to non-detect.

6.3.3 Lead (Figure 6-1D)

Sample locations with the more elevated concentration of lead occur in the Dillon Duck feature and in the nearby tidal channel bordering the northern Site uplands, County landfill, and firing range. Concentrations are typically in excess of 100 mg/kg in these locations, whereas elsewhere the condition is consistently in the range of 10 mg/kg to 50 mg/kg.

Lead concentrations in sediment within the Morrison Slough marsh were all in the range of 10 mg/kg (or less) to 50 mg/kg.

6.3.4 Total PAHs (Figure 6-1E)

The contaminant distribution for total PAHs is consistent with other COCs previously described, with the more elevated conditions present in the tidal channel areas of the Eastern Creek, LCP Ditch, in the western segment of the Western Creek Complex (headwater portion of the channel), in the middle portion of Purvis Creek, and in the tidal channel bordering the northern uplands. At these locations, the concentrations of total PAHs are generally in the range of 1 mg/kg to 5 mg/kg. The majority of the marsh flats in the LCP estuary are low to non-detect for PAHs, as is the Morrison Slough marsh flat area west of the Turtle River.

7 CHEMICAL TRANSPORT AND FATE

7.1 Overview

This section discusses chemical transport processes that explain the distribution of COCs within the LCP estuary. The majority of COC mass released into the estuary would have occurred during past manufacturing operations pre-dating the Federal Water Pollution Control Act (or Clean Water Act) amendments of 1972, involving discharge of untreated wastewater to the estuary. This was the standard of practice of that manufacturing era. Numerous elements of source control have been implemented at the Site since that time, such that current overland transport from uplands to the marsh is considered nominal. Further discussion of transport and fate processes is presented below.

Section 7.2 describes overland transport processes between the uplands and marsh. Section 7.3 describes groundwater transport processes between the uplands and marsh. Section 7.4 includes a description of overall fate and transport processes within the estuary and provides a general Conceptual Site Model (CSM) for the site.

7.2 Overland Transport Processes between the Uplands and the Marsh

Much of the current nature and extent of contamination within the LCP marsh reflects historical conditions and industrial practices/operations in the upland setting of the Site. Table 7-1 and Figure 7-1 show historical point sources and overland discharge routes of entry that have been identified at the site. Table 7-1 also identifies two primary routes of entry into the marsh, including sewer discharges from process sewers or stormwater sewers (including sewers that were discovered during past removal actions), and overland runoff. Groundwater transport into the marsh is another potential COC transport pathway that continues to be evaluated and is discussed in Section 7.3.

All known non-groundwater upland sources (i.e., all sources identified in Table 7-1, associated with historical industrial discharges and overland runoff) have been remediated. Descriptions of these sources and their contributions to marsh contamination are provided below.

7.2.1 Historical Releases during the Manufacturing Era from Process and Storm Sewer Discharges

During the period of active manufacturing at the Site, process and storm sewer discharges from the on-Site operations entered the near-shore marsh at several locations along the Site shore.

Most of the process/storm sewer lines were located in the southern portion of the Site, especially those serving the chlorine plant (Figure 7-1).

One of the sewer lines is believed to have served areas in the former ARCO community (the community built by ARCO to support the refinery operation at the Site); it passed into the South API Separator and then into the marsh. This South API Separator tank once contained several feet of sludge characterized by elevated concentrations of mercury, Aroclor-1268, and other Siterelated constituents. The sludge was removed from the tank during the upland removal action completed in 1997 and the API Separator was closed in place.

Another pipeline is believed to have been present in the northern part of the Site uplands, connected to another API Separator (the "North" tank) located along the marsh edge. Sludge was also removed from this API Separator and the tank was closed in place during the removal response action completed in 1997.

Two process sewer lines were associated with the chlorine plant, directing process wastewater to the Outfall Canal and to the Outfall Pond. Overflow from the settling pond went into the LCP Ditch. This process wastewater was discharged to the sewer lines without treatment during early industrial operations (up until the early 1970s) in accordance with standard industrial practices of that era. The chemical characteristics of this untreated wastewater can be inferred from the chemical characteristics of the first Brine Mud Impoundments constructed in the early 1970s (these impoundments received sludge from wastewater of the chlorine plant operation). Sludge in Brine Mud Impoundment No. 1 contained mercury and Aroclor-1268 at concentrations over 1,000 mg/kg. Some of the mercury and Aroclor-1268 chemical contributions to the marsh area can be attributed to the composition of this wastewater discharge. A storm sewer line also drained into the Outfall Pond.

During the operation of the chlor-alkali plant, two mercury cell buildings housed approximately 100 cells that were used in the production of bleach, soda, gas, and acid. Beginning around 1970, wastewater was diverted via concrete sloping floors to a sump and then to the on-site wastewater treatment plant for treatment prior to off-shore permitted release. The two mercury cell buildings were demolished and the concrete slab was capped to prevent future mercury emissions. The cap was planted with a Bermuda grass surface that is routinely maintained.

7.2.2 Historical Surface Runoff and Erosion

During the manufacturing operational period on the Site, chemicals likely migrated via storm-induced runoff and erosion across contaminated surface soils and exposed process waste disposal areas. Most notable, in the southern portion of the Site was a land disposal unit known as the FFDA (Figure 7-1), which contained elevated concentrations of mercury, PCBs and other Site-related constituents, and spent graphite anodes (impregnated with Aroclor-1268); the spent graphite anodes once were used as riprap for the outfall pond berm/weir and were also present scattered throughout the FFDA. The FFDA was first developed in the early 1950s and was used by the Dixie O'Brien Paints manufacturing operations on the Site. Peak tidal periods routinely inundated the FFDA, potentially washing residual surface materials into the adjacent marsh.

Lead contamination was present in the uplands at two primary locations—one location was the South API Separator (near the FFDA) and the other location was in the northwest portion of the uplands (known as "Quadrant 3" in the uplands HHBRA) where oil refining operations occurred. The South API Separator and the Quadrant 3 area upland soil sources were addressed during the uplands removal action completed in 1997.

7.2.3 Upland Source Mitigation and Control Measures Instituted Since 1994

Source control activities began with the construction of the brine mud impoundments in the early 1970s, and treatment of wastewater from the chlorine plant operation. Source removal began at the Site in early 1994 following the shutdown of manufacturing operations. Early actions involved construction of a network of containment berms to capture storm water runoff across the Site and to prevent its discharge to the estuary. Water retained behind the berms was pumped to holding basins and treated prior to discharge.

Removal (with offsite disposal) of process waste impoundments and contaminated soils areas (including the FFDA) was initiated in early 1995 and continued through 1997. Storm and process sewer manhole sumps were cleaned, and a concrete-based flowable fill was used to close the sewer network. Excavated areas were backfilled with clean borrow fill soils to restore grade. Collection and treatment of storm water runoff was no longer necessary after the uplands cleanup was completed and the runoff was sampled clean by the EPA. The two mercury cell buildings were razed and the concrete slab was capped to prevent future mercury emissions. The area of the former cell building will be addressed as part of the OU-2 Feasibility Study. The final element of the source mitigation involved excavation and restoration of approximately 13 acres of marsh flats bordering the FFDA and sewer discharge points, as well as dredging portions of the LCP Ditch and Eastern Creek.

7.3 Groundwater Transport Processes Between the Uplands and the Marsh

Groundwater within the surficial water-bearing zone (upper 50 ft) underlying the Site uplands contains inorganic and organic chemicals associated with past upland disposal practices. Groundwater flows from east to west and discharges into the estuary. The area of most elevated concentrations is beneath and west of the former Mercury Cell Buildings (in the Caustic Loading Area), where a "caustic brine pool (CBP)" exists, characterized by elevated concentrations of mercury and other metals due to the prevailing geochemical conditions; i.e., high pH (>10 standard units) and low oxidation reduction potential (ORP). The physical-chemical properties of the CBP are described in numerous past deliverables associated with the groundwater OU.

Groundwater seeps were first noted during the initial Site characterization studies in 1995, occurring west of the Brine Mud Impoundments on the southwest part of the Site (Figure 7-2A). Discolored groundwater (owing to the high dissolved organic carbon content typical of the

groundwater in the southern portion of the Site) has been observed to seep along the marsh edge where the marsh clay was absent and the underlying sand exposed. Seepage events were observed to occur during high water table conditions following extended or intense rainfall events. Depending upon the intensity and duration of the rainfall event, the seepage occurs mostly at point sources; however, a seepage face along the southern shoreline area depicted in Figure 7-2A is probable at times. Groundwater along this seepage face has been sampled by lysimeters in 2001 and 2003 and is characterized by mercury concentrations of less than 10 micrograms per liter (µg/L) (EPS, 2009).

Seepage events occur sporadically throughout the year and are typically brief (on the scale of a few days). It should be noted that, while groundwater seepage is a potential pathway into the upland fringe marsh areas, any transport is likely attenuated by the dense organic rich clay sediments along the marsh (see Section 7.4 for discussion of processes related to fate and transformation).

Groundwater transport from the uplands toward the marsh occurs within the Satilla Sand Aquifer beneath the marsh and results in discharge of groundwater upwards through the broad extent of the marsh sediments. Based on groundwater level measurements taken during low-tide events, there is an upward gradient through the sediments during low tide. During flood tide, this gradient is reversed, based on measured groundwater head elevations and known tide elevations. Such gradient reversals in marsh systems create a "hyporheic" zone by introducing surface water to the groundwater aquifer surface, and into the marsh sediment pore water.

Groundwater / surface water interactions are attenuated by the marsh sediment. As shown in Figure 3-4 and Drawing 1, marsh sediment thickness varies across the Site and averages 7-8 feet. The thinnest zones of marsh sediment are located adjacent to the uplands and are 2.5 to 6.5 ft thick (Figure 3-4). Measured hydraulic conductivities of the marsh clay are consistently low (1.3x10⁻⁷ to 1.8x10⁻⁸ cm/s) (GeoSyntec, 1997) and texture is consistently fine grained (Figure 3-6). However, variability in marsh thickness, TOC, and PSD may be greater than indicated by the point measurements conducted at the site. Thermal IR measurements were performed to provide further insight into marsh continuity.

7.3.1 Sampling to Identify Groundwater-Based Transport Flow Paths to the Estuary

In order to determine whether preferential groundwater pathways exist that could result in focused groundwater discharge in the marsh, a thermal IR study was conducted on June 15, 2009 (Stockton Infrared Thermographic Services, 2009). This study identified 14 areas of focused groundwater discharge or seeps at the marsh surface, near the marsh shoreline, and along the channel edges. Only seeps north of the causeway, specifically Seeps 3 and 5, result in groundwater discharge with a thermal signature extending beyond the immediate vicinity of the seep. The remaining seeps identified in the thermal IR study show a low intensity of groundwater discharge. These seeps are isolated and do not form a thermal trace that impacts the temperature in a marsh surface channel.

The presence of seeps raised the concern that the groundwater transport pathway into the marsh, via the seeps, may be significant. To address this concern, a sampling program was designed and implemented to determine whether seeps in the marsh flats represent preferential flow paths for elevated concentrations of COCs. During a meeting on August 27, 2009, that included Honeywell, USEPA, and GAEPD, eight of the 14 seep locations were chosen for the deployment of pore water samplers, or "peepers" (Figure 7-2A). In accordance with the *Seeps Investigation Workplan* (EPS, 2009), peepers were placed at two depths within each of the identified seep areas to examine the COC pore water concentrations in the marsh at each location. The peeper study results are shown in Tables 7-2 (metals), 7-3 (PAHs), and 7-4 (Aroclor-1268) and Figure 7-2B.

Aroclor-1268 was non-detect at all seep locations except 11S and 10D, where Aroclor-1268 was detected at 0.012 μ g/L and 0.009 μ g/L, respectively. The concentrations of total PAHs were below 1.5 μ g/L in all pore water samples, ranging from 1.3 μ g/L to 0.4 μ g/L and averaging 0.64 μ g/L. Mercury concentrations in the seeps were below 0.01 μ g/L, except at three shoreline locations: Seep 10S measured 0.87 μ g/L, Seep 11S measured 0.74 μ g/L, and Seep 11D measured 6 μ g/L.

The peeper investigation targeted locations where the IR imagery results showed the greatest potential for groundwater seepage into the marsh. Thus, the approach was inherently conservative, targeting the greatest potential for contaminant migration into the marsh. The peeper results suggest that transport of mercury, lead, total PAHs, and Aroclor-1268 via focused groundwater pathways in the marsh result in nominal concentrations at the point of discharge.

7.3.2 Conceptual Site Model of Groundwater-Based Transport to the Estuary

The groundwater CSM includes local groundwater flow from the uplands into the salt marsh along four types of flow paths, as illustrated in Figure 7-3. Each groundwater flow path is discussed in this section. COCs that are transported along each flow path encounter a sequence of geochemical conditions that affect the fate of the COCs as they are transported.

Groundwater migrating to the marsh from the uplands must cross a vertical plane parallel to the marsh boundary. The groundwater COC contribution across this vertical plane is divided among the four groundwater pathways listed below. Shallow groundwater in the Satilla Aquifer, down to the cemented sandstone, migrates towards the marsh, approximately perpendicular to the marsh boundary. Groundwater pathways are as follows from longest to shortest:

• Flow Path to Purvis Creek and Beyond: The longest flow path is from the uplands to Purvis Creek and beyond. This path is dominated by water that begins near the bottom of the Satilla Sand aquifer at the marsh boundary and is transported more than 1000 ft within the Satilla Sand. The groundwater enters the marsh sediments from below. Discharge may occur as diffuse flow through the marsh sediments, or through focused seeps that emanate in Purvis Creek.

- Flow Path to Marsh Flats and Intertidal Channels: This flow path begins with groundwater at depth along the marsh boundary. The groundwater is transported within the aquifer and enters the marsh sediments from below. Discharge through the marsh sediments may occur as diffuse discharge through the marsh sediments, or through focused seeps.
- Flow Path to Restored Marsh Area: This flow path begins at shallow depths along the marsh boundary; groundwater is transported less than 500 feet from the upland within the aquifer. The groundwater then enters the marsh sediments from below. Discharge through the marsh sediments may occur as diffuse discharge through the marsh sediments, or through focused seeps.
- Flow Path to Near Shore Seeps: The shortest flow path between the upland groundwater and the marsh leads to near shore seeps, such as those that have been identified and sampled by lysimeters. This transport flow path is dominated by the shallowest groundwater in the aquifer along the marsh boundary. The groundwater may be expressed at the surface after intense rainfall events. The distance of transport within the aquifer is short and the discharge to the surface may be in an area where marsh sediments are thinner than out on the marsh flats.

Each of these flow paths encounters lithologic and biogeochemical zones that affect the fate of the COCs being transported. The major differences between the flow paths are related to the residence time of the groundwater in the various lithologic and biogeochemical zones. Along each flow path, the zones encountered are as follows: the aquifer, the marsh sediments below the root zone, and the marsh sediments within the root zone. Upon discharge to the surface, direct mixing with tidal surface water occurs. The more focused the discharge (i.e., as a seep), the higher the potential COC concentration, but also the greater the influence of surface water dilution at the point of discharge to the surface water. Conversely, diffuse discharges upwelling through the sediment bed will be subject to more attenuation within the sediments, and also are subject to dilution at the point of discharge to the surface water.

In order to evaluate the quantity of mass being transported by these groundwater pathways, a transect-based mass flux calculation known as the "Transect Method" was employed (ITRC, 2010), as illustrated in Figure 7-4. The Transect Method relies on groundwater samples collected along a transect perpendicular to and intersecting a groundwater plume. Groundwater samples are collected from monitoring wells within the plume transect. Groundwater data is interpolated across the transect plane to map COC concentrations in the transect plane; the resulting interpolation map represents the COC concentration distribution in the transect plane at the time of sampling. Next, the transect plane is divided into sub-areas that represent discrete areas of uniform concentration and uniform groundwater flow discharge. The mass discharge is simply the sum of the mass flux calculations (i.e., flow in L/d x concentration in $\mu g/L = mass flux \mu g/d$) from each subarea.

The Transect Method was applied to the LCP estuary using groundwater samples from wells located along the upland boundary of the marsh, to quantify the mass of COCs at the marsh

boundary, migrating towards the marsh through groundwater flow paths described in the groundwater CSM. Initial application of this method for mercury was completed using available chemistry data collected from upland wells located at the marsh boundary. That analysis indicated that the mass of mercury transported by the groundwater flow paths toward the restored marsh area was insufficient to account for the measured mercury in the restored marsh. This preliminary finding was consistent with the hypothesis of tidal redistribution of in-channel sediment into the restored marsh, described in Section 7.4.

In May 2012, the upland wells along the plume transect and supplemental groundwater wells were resampled to update the Transect-Method analysis. The selection of upland wells sampled in 2012, sampling methods, and analytical constituents and methods were reviewed with EPA and GAEPD; the consensus of the review meeting was incorporated into a groundwater monitoring work plan (EPS, 2012). The 2012 groundwater data was used to update the Transect Method analysis, to calculate the mass of COCs being transported by groundwater to the marsh. Results of this analysis will be reported in the FS for OU1.

7.4 Fate and Transport Processes within the Estuary

Chemical fate and transport processes are discussed below for COCs, including (1) chemical transformation processes, (2) sorption and precipitation processes, which can limit chemical mobility and bioavailability, and (3) particulate transport process that contributed to the current distribution of COCs in the marsh.

7.4.1 Chemical Transformation Processes

Mercury, PCBs, and PAHs are subject to chemical transformation processes within sediments that can affect their fate and transport within the estuary. As a divalent metal, lead undergoes geochemical processes that affect its mobility and bioavailability.

7.4.1.1 Mercury Transformation Processes

An important chemical transformation process for mercury is its methylation to MeHg; MeHg is more bioaccumulative and toxic than inorganic forms of mercury. Mercury methylation is mediated by sulfate-reducing bacteria, with methylation rates affected by a variety of environmental parameters including the presence and availability of natural organic carbon, anaerobic sulfate-reducing conditions, and bacteria that can methylate mercury. Conditions in estuarine marshes favor the growth of sulfate-reducing bacteria and thus mercury methylation, because seawater supplies abundant sulfate and marsh plants and sediments supply abundant, easily degradable organic matter. Though these individual processes and the kinetics of mercury methylation are difficult—if not impossible—to measure in the field, the fact that MeHg has been measured in sediment is sufficient to recognize that conditions for mercury methylation exist at the Site.

Formation of inorganic mercury precipitates is relevant because inorganic mercury is the dominant form of mercury in the estuary (i.e., MeHg concentrations were <0.05 mg/kg, whereas total mercury ranged from <0.05 to 5 mg/kg in most marsh areas and from 5 mg/kg to >25 mg/kg in various marsh channels). Thus, when considering mercury transport and the current distribution of mercury in the estuary, it is helpful to understand the inorganic geochemistry of mercury. The formation of elemental mercury and dimethylmercury also are relevant transformation processes, because these forms are volatile; their formation thus provides a theoretical mechanism of slow reductions of sediment mercury concentrations over time via dispersion into the atmosphere. Sulfate reducing bacteria metabolize organic substrates in sediment where sulfate is used as the terminal electron acceptor, resulting in its reduction to hydrogen sulfide (H₂S) under anaerobic conditions. A metabolic byproduct of this process is the water-soluble methylmercury (Me₂Hg).

Several factors play a role in mercury methylation in estuarine and marine sediments, including the type and quantity of microbial organic substrates, the bioavailability of mercury, and the geochemistry controlling sediment redox dynamics. In estuarine environments the supply of sulfate and the presence of easily degradable organic matter favor the growth of sulfate-reducing bacteria and mercury methylation (Drott et al. 2008). In wetlands with high vegetation root densities, an abundant, labile source of organic carbon is available to methylating bacteria by plant exudation (Windham-Myers et al. 2009).

The methylation process is somewhat self-regulating based on the availability of sulfate and the antagonistic role of H_2S produced under reducing conditions, inhibiting microbial metabolism. The occurrence of cyclical water-level fluctuations that aerate anoxic sediments also control mercury methylation by oxidizing sediments resulting in MeHg demethylation while maintaining a continuous supply of sulfate and organic substrates to maintain sulfate reducing conditions. Under this oxidation and reduction (redox) process, the demethylation of mercury can occur in the same settings spatially and kinetically as mercury methylation, whereby MeHg is converted to inorganic mercury predominantly by microbial processes (Merritt and Amirbahman 2009).

7.4.1.2 PCB and PAH Transformation Processes

Both PCBs and PAHs are subject to environmental degradation processes (Magar et al. 2010). Environmental degradation of PCBs is relatively slow but can contribute to natural attenuation over the long term. Highly chlorinated PCBs (such as those occurring at the site) are degraded through reductive dechlorination processes, which occur in anaerobic subsurface sediments. Conditions that favor PAH biodegradation include availability of oxygen, nutrients, and warm temperatures. Thus, conditions at the marsh surface are generally favorable to PAH biodegradation.

7.4.1.3 Lead Transformation Processes

Divalent metals such as lead (and mercury) can be sorbed, complexed, or precipitated in multiple inorganic phases. For example, under anaerobic, sulfide-rich conditions, divalent metals are

sequestered as metal sulfides. Under aerobic conditions, they have a strong affinity for metal oxides of iron and manganese. Metals also can be adsorbed to clays. The upper zone of the marsh consists of organic clay that likely contributes to lead sorption. Oxidation also can increase lead solubility and bioavailability.

7.4.2 Sorption and Precipitation Processes

By definition, all persistent sediment contaminants are susceptible to biotic and abiotic processes that reduce mobility and bioavailability; these are generally sorption and precipitation processes (Fuchsman et al. 2012). These processes also contribute to attenuation of COC concentrations in sandy aquifer soils at various depth intervals along the groundwater flow path.

Sorption to organic carbon is the primary mechanism controlling the mobility and bioavailability of PCBs and PAHs in sediment, and also one of several mechanisms affecting bioavailability of divalent metals, including lead and mercury. Organic carbon is abundant in marsh habitat (e.g., detritus within the Spartina mud flats and dissolved organic carbon (DOC) from plant exudates, specifically fulvic and humic acids within the root zone of sediments). Sorption to soot, pitch, coke, and other black carbon forms can greatly decrease bioavailability of many hydrophobic organic compounds compared to amorphous organic carbon (Cornelissen et al., 2005).

Divalent metals can be sorbed, complexed, or precipitated in multiple inorganic phases, depending on the redox conditions and sediment geochemistry. Supplemental studies performed in 2002 and 2003 involved mercury and lead analyses of sediment extracts obtained using SEP methods. SEPs are chemical extractions used to remove metals from specific solid-associated phases. Progressively stronger reagents are used to solubilize metals from increasingly recalcitrant phases. The SEP is a line of evidence to help determine the fate of chemicals which may be sequestered or immobilized after being released to the environment through natural geochemical processes. A summary of this study is provided below; the full study is available in the Comprehensive Report of Estuarine Ecological Monitoring at the LCP Chemicals Superfund Site, 2002-2003 (MWH, 2005).

The applied SEP included five sequential extractions (F1 to F5), summarized in Table 7-5 and briefly described as follows. The water-soluble fraction (F1) represents the fraction of metal that is weakly sorbed and/or readily soluble in water. The "stomach acid" fraction (F2) solubilizes sorbed and/or precipitated metals sensitive to acidic conditions that might be expected in the human stomach. The third fraction (F3) targets metals complexed with carbon. Metals that are strongly complexed, or form stable precipitates with sulfides, or associated with the mineral lattice are present in fractions F4, F5, and F6, respectively. Thus the F1 through F6 fractions capture the progression of metals binding in the environment.

Total mercury concentrations (sum of the SEP fractions) during the 2002 and 2003 monitoring events ranged from approximately 0.027 mg/kg to 132.25 mg/kg. SEP results for Mercury can be summarized as follows:

- Less than 1% of mercury was present in the water-soluble fraction (F1) for all samples tested
- The sum of F1 (water soluble) and F2 (hydrochloric acid digestible fraction) is also less than 1% of the total mercury for all samples tested, suggesting that mercury in these sediments may have a limited bioavailability and mobility as free ions.
- The F3 (organo-complexed) fraction accounts for 37.0% (on average) of the total mercury, indicating the high organic content of the marsh root mass is acting as a sink for released mercury.
- The largest percentage of the total mercury was associated with the F4, strongly complexed fraction typical of metal sulfides (56.9% on average).
- Mercury was also associated with the F5 (cinnabar) fraction (generally in the range of 5 to 10%), indicating a portion of the mercury may be relatively immobilized through the precipitation of insoluble metal sulfide minerals.

Fractionation results were supported by mineralogical analysis that indicated that metal sulfide minerals (pyrite) were present at approximately 4% to 7% by weight. Although cinnabar was not directly identified (i.e., concentrations of mercury are orders of magnitude smaller as compared to iron, and solid phases containing mercury cannot be detected with the SEP methods used), the presence of pyrite indicated that conditions conducive to the precipitation of mercury sulfides are present in sediments. The fractionation of mercury into the organo-complexed fraction (F3) was also supported by mineralogical analysis that indicated organics ranging from approximately 9 to 25 percent by weight, and TOC analysis. The strongly complexed fraction (F4) may include most of the non-crystalline inorganics (e.g., iron oxides) that were identified in the mineralogical analysis. Iron oxides have been shown to sequester mercury in a comparable wetland at the Savannah River Site in Aiken, SC (Kaplan and Knox, 2002). The SEP results for mercury are most relevant to understanding potential sequestration of inorganic mercury; however, mercury bioavailability is also strongly related to the net extent of mercury methylation. As noted in Sections 7.4.1 and 7.4.2, mercury bioavailability is best understood through measurements of mercury bioaccumulation, which is discussed in Section 8.

For the 2002 monitoring event, lead concentrations were analyzed in the same SEP extracts used for mercury. Total lead concentrations (SEP sum) were low and ranged from approximately 0.02 mg/kg to 2.4 mg/kg. An estimate of the lead partitioning in sediments was developed using the same approach as described for mercury. SEP results for lead can be summarized as follows:

- The water soluble fraction of lead (F1) was generally less than 1% of total concentrations.
- On average, 51.7% of the total lead was associated with the hydrochloric acid extractible (F2) fraction.
- Only a small percentage of the total lead was associated with the F3 fraction (organo complexed phase).

- On average, 30.8% of the total lead fractionation was recovered in the strongly complexed fraction (F4), indicating that iron oxides (dissolved in this fractionation step) likely contribute in sequestering lead at the Site.
- On average, 9.7% of the total lead was associated with the F6 lattice fraction likely the result of sulfide precipitation (e.g. galena).

The SEP method described above should not be confused with analyses of acid volatile sulfides (AVS) and simultaneously extracted metals (SEM), which are often used to understand divalent metal bioavailability in sediments (EPA 2005). The AVS/SEM approach focuses specifically on sulfide as a binding phase for divalent metals.

To the extent that metals are sequestered in anaerobic sediments, it is also useful to consider whether changing redox conditions, either due to sediment resuspension or tidal cycling, could cause sequestered metals to become mobilized. Resuspension of anoxic sediments may cause oxidation and acidification (if sulfide were originally present), which may increase the mobility and bioavailability of previously sequestered divalent metals (Caetano et al., 2002; Calmano et al., 1993). However, Cantwell et al. (2008) found minimal release of dissolved metals upon resuspension of metal-contaminated, estuarine field sediments or spiked sediments containing higher sulfide concentrations. Similarly, Caille et al. (2003) showed that, while mercury and lead were released from resuspended sediments, they were rapidly re-adsorbed.

7.4.3 Sediment and COC Transport within the Estuary

The surface water CSM is influenced by the tidal hydrodynamics within the LCP estuary. Tidal flows are a key mechanism of historical contaminant transport within the estuary, and also influence the behavior of COCs in the marsh today. A surface water hydrodynamic model is being constructed to understand marsh flows, and to further validate the surface water CSM described in this section. The model will be incorporated into the FS and will serve as an engineering tool to predict marsh velocities under current conditions and for remedies proposed in the FS.

The "creeks" and "rivers" in the marsh are unique estuarine features that do not "flow" in the sense of upland freshwater creeks and rivers. Rather, these channel features are driven by tidal forces. During flood tides, water is pushed into the tidal channels and once reaching the top-of-bank elevation, water flows onto the marsh flats. It then drains from the marsh back into the tidal channels on the ebb tide cycle. The water exchange is mostly a backward/forward oscillation. Larger channels are more prone to actual water exchange during each tidal cycle.

This process of water conveyance through the creeks and rivers to the marsh flats had a strong influence on the flow velocities that occur within the marsh, and thus on the distribution of COCs in the marsh. The average water flow velocity (m/s) can be calculated by dividing the flow rate (m³/s) by the cross sectional area (m²) of flow. As tides increase, early in the tide cycle and before reaching the top-of-bank elevations, flows are confined to the area of the creeks and

channels. However, the moment that the tidally influenced flows overtop the banks of the creeks and rivers, the available cross-sectional area increases rapidly. This rapid change in the cross-sectional area of flow results in an immediate reduction in flow velocities as water transitions from creeks and rivers to marsh flats. Flow velocities are further reduced on the marsh flats due to the presence of marsh grasses that provide increased friction or resistance to the flow of water. This flow pattern is depicted, in part, in Figure 7-5. The early-stage flood tide and late-stage ebb tide are periods of highest velocity and the highest potential for conveyance of sediment particles in the marsh system. During late-stage flood tides and early-stage ebb tide, the marsh is flooded; velocities in the marsh flats (represented by yellow arrows) are relatively low and limit the conveyance of sediment particles, except for very fine-grained particles that resist settling even under low-velocity conditions.

The current distribution of mercury and Aroclor-1268 is consistent with the surface water CSM. Mercury, Aroclor-1268, and other site-related constituents associated with the FFDA and untreated discharge from the LCP ditch entered the ditch as particulate-bound chemicals, or became bound to sediment particles soon after entering the marsh, due to the prevailing geochemical conditions in the marsh. Ultimately, the transport of these chemicals within the marsh depended on the transport of sediment particles to which they were bound. Dissolved transport of COCs within the estuary is expected to be minor in comparison to transport of sediment-bound COCs, due to the low solubility of Aroclor-1268 and of divalent metal precipitates.

As discussed in Section 3.2, the channel sediments predominantly consist of clayey silts. Fine particles and the associated chemicals have the potential to be suspended and transported during high creek tidal velocities. Thus, the cycle of flood and ebb tides would have contributed to the upstream and downstream transport of COCs within the channels. The delineation of creek COC concentrations discussed in Section 4.3 is consistent with this CSM. High COC levels generally occur in the marsh channels, with the highest concentrations measured in the channels closest to the point of release (i.e., in the LCP ditch and the eastern creek that boarder Domain 1). With increasing distance from upland sources, COC concentrations generally decrease in the creeks, due to such processes as dilution with cleaner sediment and dispersion. Vertical COC profiles show that elevated concentrations are typically confined to the top 0.8 ft and decrease to non-detect levels below depths of approximately 0.8 ft. These vertical distributions suggest that the creeks are not highly depositional environments that contribute to the burial of contaminants over time. Rather, the continual tidal forces likely result in shallow erosional and depositional patterns that historically reworked the top few centimeters of the surface sediment over time.

During high tide, suspended contaminated particles were transported over the banks into the marsh. However, once in the marsh, the transport of chemicals into the marsh flats would have been limited by the decreased water velocity. Following deposition, sediment cohesion and consolidation processes would have rendered particles less susceptible to resuspension and transport over time. The distribution of COCs in the marsh provides a line of empirical evidence that supports the surface water CSM. The highest concentrations of mercury and Aroclor 1268 in the marshes are predominantly found along the banks of Eastern Creek and LCP Ditch in

Domains 1 and 2, where sediments with elevated contaminant concentrations would have deposited during high tide events.. In western Domain 2, and in Domains 3 and 4, much lower COC concentrations were measured in the marsh flats. The Domain 1 marsh area underwent remediation in 1997-1998; because of its proximity to the point of release, surface sediment concentrations in the 13-acre remediated marsh area were significantly elevated compared to the rest of the marsh.

The low recontamination of the remediated area in Domain 1 also is consistent with the surface water CSM. One of the supplemental studies conducted during the 2003 ecological monitoring event involved collection of sediment across the surface of the 13-acre marsh flats remediated and restored in 1999. Although the restoration involved the use of clean backfill soils, low concentrations of mercury and Aroclor-1268 (on average less than 1 mg/kg) were reported from the 2003 sampling event. Feagan et al. (2009) reported that localized erosion along the edges of tidal creeks redistributes sediment mass within an estuary. This is believed to have occurred in 1998-1999, following the removal action in the Eastern Creek, where bank sloughing was observed after the mechanical dredging operation. Typical concentrations of mercury and Aroclor-1268 were in the tens of mg/kg along the bank, and this would readily explain the low concentration (in the range of 1 mg/kg) of these constituents identified in the nearby remediated marsh flats during the 2003 supplemental study. This "re-contamination" of the marsh surface is explained by the tidal redistribution of the sloughed bank sediment onto the restored marsh.²

.

37 October 2012

² Based on the identification and remediation of historical sources (described in Section 7.2 and Table 7-1), there are no ongoing overland sources of contamination to the marsh. Groundwater, however, is being evaluated as a potential contributor. With respect to groundwater, the current hypothesis that the dominant contributor was overland particulate transport is consistent with the distribution of both Aroclor-1268 and mercury in the remediated area and in the adjacent Domain 1 marshes and creeks.

8 RISK ASSESSMENT SUMMARY

8.1 Introduction

The HHBRA and a BERA were conducted as components of the RI at the Site, which are incorporated into this RI by reference. These risk assessments evaluate baseline risks (i.e., risks that would exist if no remediation were applied) to human and ecological receptors in order to provide a basis for determining the need for remedial action.

Risk assessment is a regulatory process that uses information about the toxicity of chemical constituents to estimate a theoretical level of risk for humans or ecological receptors that might be exposed to those substances. This process is used to determine if levels of constituents in environmental media pose an unacceptable risk as defined by regulatory standards and requirements. When reviewing the results of any risk assessment it is important to recognize that the risk estimates are intended to facilitate those determinations, but are not necessarily predictive of adverse health effects for any person or ecological receptors.

This section summarizes the HHBRA and BERA. The full human health and ecological risk assessment reports were submitted under separate cover (EPS, 2011; Black and Veatch, 2011a).

8.2 Human Health Risk Assessment

8.2.1 Overview

The initial draft HHBRA was prepared in 1997 and a revised HHBRA prepared in 1999 (Geraghty & Miller, 1999). Those reports evaluated human health risks in the estuary and upland portions of the Site. In 2005, EPA segregated the upland and estuary into separate operable units and a stand-alone HHBRA was subsequently prepared for the estuary (OU1). The final version of the OU1 HHBRA was submitted to EPA and GAEPD in August 2011 and was approved by EPA in a letter dated November 30, 2011 (EPA, 2011).

The OU1 HHBRA followed the risk assessment framework outlined in EPA's Risk Assessment Guidance for Superfund (RAGS), Volume I, Part A (EPA, 1989) including updates and supplemental guidance. The overall goal of the HHBRA was to develop essential scientific information that can be used in decision-making regarding the LCP Chemicals Site estuary in support of an evaluation of the need for remedial action. To accomplish this goal, the specific objective of this assessment was to quantitatively evaluate whether constituents of potential concern (COPC) detected in post-removal action sediment and consumable biota in the estuary present a potential exposure and health risk to future LCP marsh trespassers or consumers of biota.

The human health risk assessment was conducted consistent with EPA guidance under CERCLA, and was a four-part process consisting of the following components:

- Data Analysis and COPC Selection The analytical data used in the risk assessment are
 presented, including the range of detected concentrations, frequency of detection in Siteassociated samples and other summary statistics. COPC are selected through
 comparisons to conservative risk-based screening levels and quantitative risk estimates
 are subsequently calculated for those constituents.
- Exposure Assessment Scenarios under which exposure to Site COPC could occur under current or reasonably foreseeable future Site uses are discussed, and a set of current and/or hypothetical receptor scenarios that provide an overall characterization of potential risks is developed. The complete exposure pathways by which receptors could be exposed to Site COPC are discussed. Conservative estimates of the intake of each COPC by each receptor through the relevant pathways are calculated.
- Toxicity Assessment A characterization of the toxicity and dose-response characteristics of each COPC is provided with regard to potential carcinogenic and non-carcinogenic effects. This step provides a quantitative representation of toxicity that can be used in conjunction with the intake information from the Exposure Assessment to characterize potential risks.
- Risk Characterization The information provided by the Exposure Assessment and Toxicity Assessment is combined to yield quantitative estimates characterizing the relationship between estimated exposures and potential toxicity. Risk estimates for potential excess cancer risk and non-cancer risk are provided and placed into context.

8.2.2 Data Analysis and COPC Selection

Analytical data from sediment and biota samples collected in the LCP estuary were used to identify COPC and to evaluate human exposure to those COPC. The initial data analysis for this HHBRA, including the identification of COPC and the derivation of exposure point concentrations (EPCs), was conducted by EPA, and the results provided to the PRP Group for use in the HHBRA (EPA, 2010a).

The sediment dataset used in the HHBRA included surface sediment (upper 15 centimeters (cm)) samples from 2000 through 2007 (i.e., following the marsh removal action of 1998-99). Sediment samples from Purvis Creek and the Turtle River were excluded as these areas remain inundated at low tide and afford no opportunity for human exposure. Sediment COPC were identified by comparing the maximum detected concentration of each constituent with the appropriate EPA Regional Screening Level (RSL) for residential soil (EPA, 2010b). The maximum detected concentrations of the inorganic constituents were also compared with two-times the mean Site-specific background concentrations. The COPC selection process for sediment is summarized in Table 1 of the OU1 HHBRA.

The biological dataset used in the HHBRA included samples of finfish and shellfish collected from the estuary adjacent to the LCP Site between 2002 and 2006 following guidance from the Georgia Department of Natural Resources (GADNR) (FTAC, 1992). The data consist of analytical results from fish species likely to be consumed by humans (e.g., red drum, spotted seatrout) as well as those less likely to be consumed (e.g., spot, striped mullet). The biological dataset also included samples of breast tissue from clapper rail, a small game bird inhabiting coastal marshes, that were collected the estuary adjacent to the LCP Site in 1995 (i.e., prior to the marsh removal action). COPC in biota were identified by comparing the maximum detected constituent concentrations in fish, shellfish, and clapper rail to EPA RSLs for fish ingestion (EPA, 2010c). The COPC selection process for fish, shellfish and clapper rail tissue is summarized in Table 3 of the OU1 HHBRA. The conceptual model is provided in Figure 3 of the OU1 HHBRA.

The COPCs identified in sediment and biological tissue are shown in the table below.

Constituents	Sediment	Fish	Shellfish	Clapper Rail
Aluminum	X			
Aroclor-1268 ⁽¹⁾	X	X	X	X
B(a)P TEQ ⁽²⁾	X			
Copper			X	
Chromium ⁽³⁾	X			
Lead	X			
Manganese	X			
Mercury ⁽⁴⁾	X	X	X	X
Thallium	X			
Zinc			X	

⁽¹⁾ Aroclor-1268 was identified as a COPC based on comparisons to the RSLs for Aroclor 1254

8.2.3 Exposure Assessment

8.2.3.1 Overview

Exposure is defined for risk assessment purposes as contact with constituents in environmental media at the outer boundaries of the body, such as the gastrointestinal tract (for ingestion route) and skin (for the dermal route). Exposure assessment is the process of measuring or estimating the intensity, frequency, and duration of human exposure to COPC. This information is integrated with estimates of EPCs in an environmental medium (e.g., sediment, fish, shellfish, or clapper rail) to quantitatively estimate the COPC intake, or dose.

To provide some understanding of the range of exposures and consequent risks, scenarios based on both reasonable maximum exposure (RME) and central tendency exposure (CTE) were

 $^{^{(2)}}$ B(a)P TEQ = Benzo(a)pyrene toxic equivalents

⁽³⁾ As a conservative assumption, chromium in sediment and biota was assumed to be in the hexavalent state, despite the reducing conditions of the sediment.

⁽⁴⁾ Although mercury and MeHg were considered separately for sediment exposure in the HHBRA, both chemical forms were assessed conservatively as MeHg.

evaluated. The RME provides an estimate of the highest reasonable exposure possible to an individual. Such an individual is defined as the RME receptor and is generally considered to be at the 90th percentile of the exposure distribution or higher, whereas the CTE provides a midrange estimate.

8.2.3.2 Human Receptors

The receptors evaluated in the OU1 HHBRA include:

- marsh trespasser
- recreational fish consumer
- high quantity fish consumer
- shellfish consumer
- Clapper Rail consumer

8.2.3.2.1 Marsh Trespasser

The marsh trespasser scenario is used to evaluate potential exposure to COPC in sediment during excursions into the marsh adjacent to the LCP Site. It should be noted that the LCP marsh is not a setting that invites trespassing. It is difficult in some areas of the marsh for humans to negotiate on foot due to very soft sediment that can result in rapid sinking; therefore the HHBRA only used data points from samples collected in more accessible areas. EPA does not have default exposure factors for marsh human site visitor or trespasser scenarios; thus site-specific judgment was used to estimate appropriate exposure inputs that would not underestimate the risks. The risk assessment assumes that a hypothetical individual visits the marsh on a regular basis over time beginning in adolescence and continuing into adulthood. The RME scenario assumes that these trespassing events occur at a frequency of 52 days/year for a total of 30 years. The CTE scenario assumes that these events occur 6 days per year for a total of 8 years. Table 7 of the HHBRA summarizes the exposure factors for the RME and CTE Trespasser scenarios.

8.2.3.2.2 Fish Consumer Scenarios

The fish consumer scenarios are used to evaluate potential exposure to COPC in fish caught in areas of the estuary proximate to the LCP Site. Fish Consumption Guidelines (FCGs) have been established by GADNR for these areas (GANDR 2011) and these FCGs are made available to the public via the GADNR website. GADNR also posts signage in areas subject to the FCGs to advise anglers about the potential hazards associated with consuming fish and shellfish from these areas.

The recreational fish consumer scenario is used to evaluate exposure to recreational anglers who consistently consume fish from the LCP estuary over a long period of time (e.g., 26 meals per year for 30 years for adults). This scenario uses data on the amount of recreationally-caught fish consumed by children, adolescents, and adults in the southeastern United States (EPA, 1997a) and assumes that all of that consumption would occur within the affected area. Table 10 of the

OU1 HHBRA summarizes the exposure factors for the RME and CTE recreational fish consumer scenario.

The high quantity fish consumer scenario is used to evaluate exposures to individuals who consume more locally-caught fish than the typical recreational angler (e.g., 40 meals per year for 30 years for adults). This scenario uses information on seafood consumption in the Brunswick area obtained by the Agency for Toxic Substances and Disease Registry and the Glynn County Health Department (DHHS, 1999). Information regarding the development of the exposure factors for the RME and CTE high quantity fish consumer scenario is provided in Appendix B of the OU1 HHBRA. These exposure factors are also summarized in Table 10 of the OU1 HHBRA.

Because the OU1 HHBRA included data on the concentrations of COPC in a variety of different fish species it was necessary to estimate the relative amounts of these different fish species eaten by local consumers. For this, recreational harvest data from the NOAA's *Marine Recreational Fisheries Statistics Survey* for Georgia coastal inland waters were used to adjust the species-specific exposure estimates based on angler success and preferences.

8.2.3.2.3 Shellfish Consumer Scenario

The shellfish consumer scenario is used to evaluate potential exposure to COPC in shellfish (e.g., white shrimp and blue crab) caught in areas of the estuary proximate to the LCP Site. As described above for fish, GADNR also develops FCGs for shellfish. The shellfish consumer scenario assumes consistent and long-term consumption of shellfish directly from the LCP estuary (e.g., 19 meals per year for 30 years for adults). This scenario uses data on the amount of shellfish fish consumed by children, adolescents, and adults in the United States (EPA, 1997a). Table 10 of the OU1 HHBRA summarizes the exposure factors for the RME and CTE shellfish consumer scenario.

8.2.3.2.4 Clapper Rail Consumer Scenario

The clapper rail consumer scenario is used to evaluate potential exposure to COPC in clapper rail caught in areas of the estuary proximate to the LCP Site. According to United States Fish and Wildlife representatives, although the clapper rail is hunted, people do not commonly consume clapper rails (Bowers, 1997, as cited in Geraghty & Miller, 1999). In addition, it is unlikely that hunters would pursue clapper rails in the vicinity of the Site due to the close proximity of more desirable and accessible areas. There are no data specific to clapper rail ingestion rates; therefore data for total wild game ingestion for children, adolescents, and adults was used (EPA, 1997a), along with the conservative assumption that clapper rail obtained from the LCP marsh comprised 10% of the total wild game ingestion. Thus, there are considerable uncertainties associated with the evaluation of this exposure pathway. Table 10 of the OU1 HHBRA summarizes the exposure factors for the RME and CTE clapper rail consumer scenario.

8.2.3.2.5 Exposure Point Concentrations

An EPC is the concentration of a COPC in a given medium to which a receptor may be exposed. EPA's ProUCL software version 4.00.02 (EPA, 2007) was used to calculate EPC for both sediment and biota. The ProUCL EPC recommendations for sediment are provided in Table 1 of the OU1 HHBRA. The ProUCL EPC recommendations for finfish, shellfish, and clapper rail tissue are provided in Table 3 of the OU1 HHBRA.

8.2.4 Toxicity Assessment

The toxicity assessment provides a description of the relationship between a dose of a chemical and the potential for an adverse health effect. The purpose of toxicity assessment is to provide a quantitative estimate of the potential inherent toxicity of COPC for use in risk characterization. For risk assessment purposes, potential effects of constituents are separated into two categories: 1) carcinogenic effects; and 2) non-carcinogenic effects.

EPA assumes that most carcinogenic constituents do not exhibit a response threshold (EPA 2005). Potential carcinogenic effects resulting from human exposure to chemicals are estimated quantitatively using cancer slope factors (CSFs), which represent the theoretical increased risk per milligram of chemical intake per kilogram body weight per day. CSFs are derived for chemicals that EPA identifies as "known" or "likely" human carcinogens and are used to estimate a theoretical upper-bound lifetime probability of an individual developing cancer as a result of exposure to a potential carcinogen.

It is generally accepted that non-carcinogenic effects of constituents occur only after a threshold dose is achieved (Klassen, 2001). Potential non-carcinogenic effects resulting from human exposure to chemicals are estimated quantitatively using reference doses (RfDs). The RfD is an estimate of a sensitive individual's daily maximum level of exposure to a constituent that is likely to be without an appreciable risk of adverse effects. EPA defines reference doses as "an estimate (with uncertainty spanning perhaps an order of magnitude) of a daily oral exposure to the human population (including sensitive subgroups) that is likely to be without an appreciable risk of deleterious effects during a lifetime" (EPA, 1989).

With the exception of Aroclor-1268, which is discussed below, CSF and RfD values specific to each COPC were obtained from the December 2010 edition of EPA's RSL Table (EPA, 2010a). The RSL Table provides a selection of constituent-specific values from a defined hierarchy of sources outlined in EPA guidance (EPA, 2003). These values are summarized in Table 21 of the OU1 HHBRA.

EPA has not developed CSFs or RfDs specific to Aroclor-1268. EPA recommends assessing total PCBs using CSFs based on toxicology studies done with several Aroclors. The RFDs for Aroclor-1254 and/or Aroclor-1016 are commonly used to assess non-cancer endpoints for other Aroclors.

For the evaluation of potential carcinogenic effects, EPA's Integrated Risk Information System (IRIS) contains two CSF values corresponding to "high risk/persistence" and "low

risk/persistence" PCB mixtures. For human ingestion of PCBs in biota and soil/sediment, IRIS recommends the use of the high risk/persistence CSF value for estimation of potential carcinogenic risks.

For the evaluation of potential non-carcinogenic effects, IRIS contains RfD values for two different PCB mixtures, Aroclor-1016 and Aroclor-1254. Information provided in the OU1 HHBRA supports the conclusion that Aroclor-1268 is more similar on a toxicological basis to Aroclor-1016 than to Aroclor-1254. Therefore, the RfD for Aroclor-1016 was used to estimate the non-carcinogenic hazards associated with exposures to Aroclor-1268.

As indicated in Section 5.11 of the HHRA (EPS, 2011), the maximum screening value for lead in marsh sediment exceeded the residential screening value for lead of 400 mg/kg (EPA, 1994). Because the maximum sediment value exceeded the screening level, lead was identified as a COPC in marsh sediment. However, the EPC for lead was 43.7 mg/kg (based on the 95% upper confidence limit on the mean (UCL)), which is nearly 10 times below the 400 mg/kg residential screening value and consequently no further risk evaluation was conducted for lead.

8.2.5 Risk Characterization

The risk characterization integrates the exposure estimates for Site receptors with the representations of the potential toxicity derived for each COPC. This integration yields quantitative estimates of theoretical excess lifetime cancer risks and non-cancer hazard quotients for COPC. These estimates provide a quantitative representation of the relationship between hypothetical exposures and potential toxic responses. The risk characterization also provides an interpretation of the potential significance of the risk estimates by comparing them to regulatory guidelines indicating the need for addressing risks and hazards.

8.2.5.1 Calculation of Excess Lifetime Cancer Risks

Theoretical excess lifetime cancer risk (ELCR) estimates for receptors are expressed as an upper-bound probability of additional lifetime cancer risk due to exposure to Site-related chemical constituents. These estimates do not reflect an individual's existing lifetime risk of developing cancer—which is, without site exposure, already between one-in-two $(2 \times 10^{-1} \text{ or } 2\text{E-1})$ and one-in-three $(3 \times 10^{-1} \text{ or } 3\text{E-1})$ (ACS, 2011)—but only the additional incremental risk that is theoretically related to exposure to Site COPC.

For each receptor scenario, theoretical ELCR estimates are calculated for each carcinogenic COPC by multiplying the lifetime average daily intake estimated for that COPC by its CSF (EPA 1989). This approach to calculating ELCR estimates incorporates the assumptions that increased risk of cancer resulting from exposure to a constituent is directly proportional to constituent intake averaged over a lifetime and there is no dose below which carcinogenic effects cannot occur. This assumption ensures that ELCR estimates for each receptor are upper-bound (i.e., the actual risk is very unlikely to be higher, and is expected to be lower).

Under the National Contingency Plan (NCP, 40 CFR Part 300, cancer risk levels for chemical constituents are evaluated in relation to EPA's target range of 10^{-4} (1 in 10,000) to 10^{-6} (1 in 1,000,000) for incremental cancer risk. Calculated upper-bound ELCR estimates less than 1×10^{-6} are considered to be insignificant, and ELCR estimates greater than 1×10^{-4} require further characterization, but not necessarily remedial action or other risk reduction measures. Risk managers can exercise discretion in interpreting these upper-bound risk estimates in the context of Site-specific conditions.

Table 8 of the OU1 HHBRA detail the ELCR estimates for the marsh trespasser scenario; Tables 12 through 17 detail the ELCR estimates for the recreational finfish consumer, high quantity finfish consumer, and shellfish consumer scenarios; and Tables 19 and 20 detail the ELCR estimates for the clapper rail consumer scenario.

8.2.5.2 Calculation of Potential Non-cancer Hazards

Potential non-cancer risks for individual COPC are expressed as Hazard Quotients (HQs) (EPA, 1989). For each receptor scenario, HQs are calculated as the ratio of the estimated daily intake of each COPC to the corresponding RfD for that COPC. Where the average daily dose estimated for the COPC exceeds the RfD, the HQ exceeds one (1). An HQ of one is typically considered a threshold requiring further evaluation since it indicates that exposure could be higher than the "no-effect" dose represented by the RfD. However, because of the conservative nature of RfDs and the uncertainties surrounding the reference dose, a HQ greater than one does not necessarily indicate that harm will occur. Where the HQ is below 1, the average daily dose for the COPC is below the RfD, indicating that an adverse non-cancer effect resulting from exposure to that COPC is unlikely.

The HQs for potential non-cancer risks for multiple COPC across complete exposure pathways and receptors HQs are summed to yield a cumulative Hazard Index (HI). Summing all of the individual COPC HQs incorporates the assumption that their risks are all additive, when, in fact, different COPC are expected to act through different mechanisms and on different target organs. The cumulative HIs are useful for rapidly excluding pathways or receptors with negligible potential for non-cancer effects (i.e., where all the COPC HQs added together do not exceed an HI of 1). EPA guidance recognizes that non-carcinogenic effects are exhibited in specific target organs and that certain chemicals can act in an additive fashion on the same organ.

An HI above one for a receptor scenario is typically considered a threshold requiring further evaluation or corrective action since it indicates that exposure could be higher than the "noeffect" doses represented by the RfD. When the HI for a receptor scenario is 1 or below, it indicates that non-cancer effects resulting from exposure to COPC are unlikely.

Table 9 of the OU1 HHBRA detail the HQ/HI estimates for the marsh trespasser scenario; Tables 12 through 17 detail the HQ/HI estimates for the recreational fish consumer, high quantity fish consumer, and shellfish consumer scenarios; and Tables 19 and 20 detail the HQ/HI estimates for the clapper rail consumer scenario.

45

October 2012

8.2.5.3 Risk / Hazard Summary

The theoretical carcinogenic risks and potential non-carcinogenic hazards estimated for each receptor are summarized in Table 8-1³.

With respect to potential carcinogenic effects, only the RME high-quantity fish consumer scenario has an ELCR estimate that exceeds EPA's target risk range of 10⁻⁶ to 10⁻⁴. The RME recreational fish consumer and shellfish consumer scenarios both have ELCR estimates equal to the upper-end of the EPA's target risk range. All of the receptor scenarios have CTE ELCR estimates below the upper-end of EPA's target risk range.

With respect to potential non-carcinogenic effects, the marsh trespasser is the only RME scenario with a cumulative HI estimate below the threshold value of one. All of the RME seafood and wild game consumption scenarios have cumulative HI estimates above one. The high-quantity fish consumer scenario is the only receptor scenario with CTE HI estimates above one.

8.2.5.4 Remedial Goal Options

EPA Region 4 guidance requires the development of Remedial Goal Options (RGOs) for all COC, which are the COPC that contribute significantly to unacceptable ELCR or HI estimates for a receptor scenario (EPA, 2000). Based on the information in the table above, the fish, shellfish, and clapper rail consumer scenarios all trigger the development of RGOs. RGOs are not needed for direct contact with sediments in the marsh trespasser scenario.

Table 23 of the OU1 HHBRA provides receptor-specific RGOs for Aroclor-1268 and mercury in finfish, shellfish, and clapper rail tissue. For Aroclor-1268, RGOs for carcinogenic endpoints were calculated based on risk targets of 1×10^{-4} , 1×10^{-5} , and 1×10^{-6} . For Aroclor-1268 and mercury, RGOs based on non-carcinogenic endpoints were developed based on target HQs of 0.1, 1.0, and 3.0.

8.2.6 Characterization of Uncertainties

Uncertainties are inherent in the quantitative risk assessment process due to the use of environmental sampling results, assumptions regarding exposure, and the quantitative representation of chemical toxicity. Analysis of the uncertainties in risk assessment provides a better understanding of the quantitative results through the identification of the uncertainties that most significantly affect the results so that risk managers are better informed when evaluating risk assessment conclusions and the need for remedial action (EPA, 1989).

In general, the most significant sources of uncertainty in the OU1 HHBRA relate to the exposure assumptions used to characterize the RME receptor scenarios, the concentrations of COPC in biota tissue used to estimate receptor intake, and the surrogate toxicity values used to characterize the potential carcinogenic risks associated with Aroclor-1268. Because

46 October 2012

³ This table is a reproduction of Table 22 of the OU1 HHBRA Report (EPS, 2011).

conservative assumptions were applied to each of these sources of uncertainty, it results in a conservative estimation of risks for the receptor scenarios evaluated. Specific examples include:

- The assumption that an individual trespasser would walk through the LCP marsh once a week for 30 years (a total of 1,560 separate events), each time getting nearly a quarter of his body covered in mud;
- The assumption that 100% of the fish and shellfish eaten by any individual would come from the areas in the immediate vicinity of the LCP Site, particularly when the GADNR FCGs and posted signage generally serve to discourage the consumption of significant amounts of seafood from the area, particularly given the number of meals assumed to be eaten consisting of fish caught in the LCP estuary;
- The assumption that a hunter would eat clapper rail obtained from the LCP marsh such that this source of clapper rail comprises 10% of the wild game that he eats; and
- The assumption that the potential carcinogenicity of Aroclor-1268 should be evaluated using the upper-bound CSF for high risk/persistence PCBs such as Aroclor-1254, when one scientific publication suggests that the tumorigenic potency of Aroclor-1268 may be at least 10-times lower (Warren et al., 2004).

The consistent use of conservative assumptions to address areas of uncertainty in the OU1 HHBRA should be considered when evaluating the need for remedial actions to address human health risks that exceed the EPA targets.

8.3 Summary of the Baseline Ecological Risk Assessment

8.3.1 Overview

The purpose of the BERA is to describe the likelihood, nature, and extent of adverse effects to ecological receptors resulting from exposure to chemicals released to the environment as a result of past Site activities. This information is used by risk managers to decide whether remedial actions are warranted to protect the environment from Site-related impacts. The EPA has established a general framework for conducting ecological risk assessment (EPA, 1998), which is illustrated in Figure 8-1. As shown in this figure, ecological risk assessment is an iterative process in which risk questions are asked, data with which to address the questions are collected and analyzed, and additional study is conducted if warranted. As commonly applied at Superfund sites, ecological risk assessment is envisioned as an eight-step process, starting with a relatively simple screening-level evaluation and proceeding to more detailed and complex investigations and analyses as warranted.

An initial draft BERA Report for the LCP estuary, based on data collected prior to the marsh removal action, was submitted to EPA in 1997 (PTI and CDR, 1997). Based in part on the data presented in that report, a marsh removal action was conducted between 1998 and 1999 in which approximately 13 acres of marsh flats nearest the sources of historical facility discharges were excavated, backfilled to restore grade, and vegetated with native marsh grasses. EPA requested

that another sampling event be performed soon after the marsh removal action to establish the post-removal baseline conditions in the estuary. A work plan for the collection of these data was approved by EPA and the fieldwork was conducted in the fall of 2000. Based on data from that sampling event, another draft BERA Report was submitted to EPA (CDR and GeoSyntec, 2001).

Honeywell subsequently conducted a multi-year ecological monitoring study in the estuary to provide data on temporal and spatial trends of chemical concentrations in sediment and biota. Beginning in the year 2002 and extending through 2007, annual monitoring was performed following the general study design established to support the 2001 BERA. A number of "supplemental studies" were also conducted during these annual events. In 2009, an updated draft OU1 BERA Report that incorporated the comprehensive dataset collected between 2000 and 2007 was submitted to EPA (CDR and EPS, 2009). In a letter dated July 2, 2010, EPA disapproved this draft and provided Honeywell with an edited version of the OU1 BERA Report that it considered acceptable for approval (EPA, 2010d). Honeywell did not concur with all of EPA's edits, particularly those related to the interpretation sediment toxicity testing results. Honeywell and EPA were ultimately unsuccessful at resolving these differences, prompting EPA to contract Black & Veatch to finalize the OU1 BERA Report. The final BERA Report was issued in April 2011 and encompasses approximately 1,000 pages of text, figures, tables, and appendices (Black and Veatch, 2011). This section presents a brief summary.

8.3.2 Data Used in the BERA

As described above, the data used quantitatively in the OU1 BERA were generated in the post-removal action ecological monitoring event in 2000 and the subsequent annual monitoring events that occurred between 2002 and 2007. The decision to use the entire post-removal action dataset, rather than just the most contemporary data, was based on an evaluation of temporal characteristics of COPC concentrations in surface sediment collected from sentinel monitoring stations within the estuary that were sampled repeatedly over that period. The general conclusion from this evaluation is that, with a few possible exceptions, there were no discernible concentration trends for the COPC at these sentinel stations. The BERA also concludes that there were no apparent temporal COPC concentration trends in biota.

The basic experimental design for the OU1 BERA was established in the work plan for the 2000 monitoring event (Honeywell, 2000), and with the exception of several unique amphipod toxicity studies conducted in 2006 to address specific risk questions, remained fairly consistent for the 2000-2007 monitoring events. This experimental design is summarized in Table 8-2⁴.

For purposes of the investigations and analyses conducted for the OU1 BERA, the LCP estuary was divided into four domains, which are depicted in Figure 3-1A.

_

48 October 2012

⁴ This table is a reproduction of Table 3-1 of the OU1 BERA Report. Additional detailed information about the specific analyses conducted at each monitoring station for each monitoring event is provided in Tables 3-2 and 3-3 of the OU1 BERA Report. The locations of the ecological monitoring stations in the LCP estuary are shown in Figures 3-3, 3-4, and 4-5 of the OU1 BERA (Black and Veatch, 2011).

- <u>Domain 1</u> is bounded by the uplands to the east, the main canal to the north and the eastern creek to the west. The marsh removal action conducted in 1998-1999 addressed sediments in the eastern portion of this domain. Domain 1 is salt marsh. Marsh grass was planted following the removal action and initially flourished. Portions of Domain 1, both within the removal area and outside of the removal area currently show evidence of the "marsh dieback" that has been observed throughout the southeast. The cause of marsh dieback is unknown, but a relationship between marsh dieback and chemical concentrations at the site is not evident; marsh dieback is prevalent in areas well beyond the LCP estuary (NOAA, 2005) and some areas of the marsh with higher chemical concentrations show no evidence of dieback.
- <u>Domain 2</u> is bounded on the east by Domain 1, the south by uplands not part of the LCP property, and the west and north by Purvis Creek and the Main Canal. Domain 2 is salt marsh with tidal creeks including the Western Creek Complex.
- <u>Domain 3</u> is bounded to the south by the Main Canal, the east by the LCP uplands, and the west and north by Purvis Creek. It is salt marsh with abundant small tidal creeks.
- <u>Domain 4</u> is the area west of Purvis Creek to the Turtle River. Domain 4 is divided into an eastern and western portion by the flow divide between creek and river.

The locations of sampling stations in the LCP estuary for surface water, sediment, and associated biota for the study years 2002-2007 are shown in Figures 5-2A through 5-2G. The figures for study years 2004-2006 show sampling locations for Blythe Island, a marsh area that was evaluated to allow environmental information generated at the LCP Site to be interpreted in a broader geographic context. Not shown on these figures are the reference locations for the investigation, which were in the Crescent River (located west of Sapelo Island) and Troup Creek (located on the eastern side of the Brunswick Peninsula).

Sediment, surface water, and biota data generated during each study event were evaluated in the BERA using mean concentrations and the 95% UCL concentrations for each domain and grand mean values for the whole estuary, as suggested by scientists from NOAA during an initial review of the OU1 BERA (Dillon, 2008).

8.3.3 Problem Formulation

8.3.3.1 Overview

Problem formulation is a planning step that identifies the major concerns and issues to be considered in an ecological risk assessment, along with a description of the basic approaches that will be used to characterize the potential ecological risks.

8.3.3.2 Ecosystem Characteristics

The estuary in the vicinity of the LCP Site is a complex and highly productive ecosystem that consists of both salt marsh and associated tidal creeks. Cordgrasses (*Spartina spp.*) are the dominant plant species in the estuary providing refuge and foraging habitat for a wide variety of fish, shellfish, and wildlife. Cordgrass leaf-blades die back annually and break into small pieces

that ultimately form a detrital layer that fosters a host of microscopic organisms such as bacteria, fungi, and algae. The tidal creeks of the LCP estuary experience the full amplitude (about 3 meters [m]) of the semidiurnal tides that occur in the Brunswick River estuary. These creeks support a variety of water-column and benthic organisms.

Benthic aquatic life indigenous to the tidal creeks include fiddler crabs (*Uca spp.*), various species of polychaete worms, amphipods, barnacles, mysid shrimp (Mysidopsis spp.), penaeid shrimp (*Penaeus* spp.), grass shrimp (*Palaemonetes pugio*), and blue crabs (*Callinectes sapidus*).

Fish species indigenous to the estuary include the mummichog (Fundulus heteroclitus), red drum (Sciaenops ocellatus), black drum (Pogonias cromis), silver perch (Bairdiella chrysoura), spotted seatrout (Cynoscion nebulosus), striped mullet (Mugil cephalus), Atlantic croaker (Micropogonias undulates), southern kingfish (Menticirrhus americanus), spot (Leiostomus xanthurus), and sheepshead (Archosargus probatocephalus). Fish may migrate from the LCP estuary to nearby areas.

The most common reptile in Atlantic coast salt marshes is the diamondback terrapin (*Malaclemys terrapin*). Several species of threatened or endangered Atlantic sea turtles including the green turtle (*Chelonia mydas*), Kemp's ridley turtle (*Lepidochelys kempi*), hawksbill turtle (*Eretmochelys imbricata*), loggerhead turtle (*Caretta caretta*), and leatherback turtle (*Dermochelys coriacea*), could also visit the estuary.

Bird species that may forage within and/or inhabit the estuary include a variety of grebes, cormorants, herons and bitterns, ibises, geese, marsh ducks, mergansers, vultures, hawks, ospreys, falcons, rails (including the clapper rail, (*Rallus longirostris*), stilts, plovers, sandpipers, gulls and terns, pelicans, skimmers, kingfishers, and passeriform birds. A threatened or endangered avian species that may frequent the estuary is the wood stork (*Mycteria americana*). Wood storks have been observed foraging in tidal creeks of the LCP salt marsh and breed at several colonies in the vicinity of Brunswick.

Mammals foraging within and/or inhabiting the estuary include various shrews and bats, raccoons (*Procyon lotor*), mink (*Mustela vison*), river otters (*Lutra canadensis*), marsh rice rats (*Oryzomys palustris*), and marsh rabbits (*Sylvilagus palustris*). The West Indian manatee (*Trichechus manatus*), an endangered species, and the Atlantic bottle-nosed dolphin (*Tursiops truncatus*), both of which are protected under the Marine Mammal Protection Act, occur in the Brunswick estuary and have been observed in Purvis Creek.

8.3.3.3 Receptors Potentially at Risk

The initial baseline problem formulation focused on risks to fish and wildlife through bioaccumulation into tissues of organisms or their potential to become exposed through ingestion of contaminated prey (Honeywell, 2001). This is consistent with the conceptual model provided as Figure 3-2 of the BERA (Black and Veatch, 2011). This emphasis was based, in part, on studies conducted in the mid-1990s that identified elevated concentrations of mercury and PCBs in fish tissue samples from Turtle River estuary and other wildlife tissue (GADNR, 1995; Sprenger, 1997), along with Site-specific sediment toxicity testing results that indicated minimal

acute toxicity to benthic invertebrates (Sprenger, 1997). However, extensive sediment toxicity testing during the ecological monitoring events between 2000 and 2007 has identified contributions to benthic toxicity from heavy metals in sediments, including lead.

8.3.3.4 Chemicals of Potential Concern

The initial baseline problem formulation for the BERA (Honeywell, 2001) identified four "major" COPC:

- Mercury (including MeHg)
- Aroclor-1268
- Lead
- Total PAHs

Information on the ecological toxicity of the COPC is provided in Section 3.6 of the OU1 BERA Report. Both mercury and Aroclor-1268 pose potential threats to upper trophic-level ecological receptors mainly via bioaccumulation in the food-web. The primary threats posed by lead and PAHs relate to their potential to cause direct toxicity to lower trophic-level organisms in the sediment and water column.

These four chemicals remain the primary COPC evaluated quantitatively in the BERA. However, based on the subsequent rounds of sampling, the COPC screening process was updated to identify other COPC in sediment and surface water samples that could potentially contribute to ecological risks. This updated screening process involved comparing maximum detected concentrations of all target analytes to conservative screening-level ecological effects values (EEVs) recommended for this purpose by EPA. Detailed information related to the updated COPC screening is provided in Appendix B of the OU1 BERA Report.

Additional inorganic chemicals were identified as COPC in surface water and/or sediment, including a number of metals, none of which have significant bioaccumulation potential. These metals were not evaluated quantitatively in the food-web exposure models, but they were considered in the evaluation of potential risks to benthic organisms.

Several additional organic chemicals were detected in a small number of samples at concentrations above the conservative EEVs, including dichlorodiphenyltrichloroethane (4,4' DDT), dioxin/furan congeners, bis(2-ethylhexyl)phthalate, 3,4-methylphenol, butylbenzylphthalate, and hexachlorobenzene. These chemicals are not quantitatively evaluated for benthic or food chain risks, but are discussed qualitatively in the OU1 BERA.

8.3.3.5 Assessment and Measurement Endpoints

Assessment endpoints are the valued attributes of ecological resources or receptors upon which risk management actions are focused. EPA defines an assessment endpoint as "an explicit expression of the environmental value to be protected, operationally defined as an ecological entity and its attributes" (EPA, 1998). Measurement endpoints are ecological characteristics that can be measured, interpreted, and related to the valued ecological attributes selected as the

assessment endpoints (EPA 1997b; 1998). The following assessment and associated measurement endpoints were identified for the OU1 BERA:

<u>Assessment Endpoint 1</u> – Viability of the benthic estuarine community.

This assessment endpoint is evaluated by three measurement endpoints: 1) comparisons of concentrations of COPC in surface sediment to Site-specific effects levels; 2) results of toxicity tests conducted with sensitive life stages of benthic biota exposed to surface sediment; and 3) evaluation of the indigenous benthic community.

Assessment Endpoint 2 – Viability of omnivorous reptiles utilizing the estuary.

This assessment endpoint is evaluated by HQs derived from food-web exposure models for diamondback terrapins (*Malaclemys terrapin*).

<u>Assessment Endpoint 3</u> – Viability of omnivorous avian species utilizing the estuary.

This assessment endpoint is evaluated by two basic measurement endpoints: 1) HQs derived from food-web exposure models for red-winged blackbirds (*Agelaius phoeniceus*); and 2) HQs derived from food-web exposure models for clapper rails (*Rallus longirostris*).

<u>Assessment Endpoint 4</u> – Viability of piscivorous avian species utilizing the estuary.

This assessment endpoint evaluated by HQs derived from food-web exposure models for green herons (*Butorides striatus*).

<u>Assessment Endpoint 5</u> – Viability of herbivorous mammalian species utilizing the marsh.

This assessment endpoint estimated by HQs derived from food-web exposure models for marsh rabbits (*Sylvilagus palustris*).

Assessment Endpoint 6 – Viability of omnivorous mammalian species utilizing the estuary.

This assessment endpoint estimated by HQs derived from food-web exposure models for raccoons (*Procyon lotor*).

<u>Assessment Endpoint 7</u> – Viability of piscivorous mammalian species utilizing the estuary.

This assessment endpoint was evaluated using HQs derived from food-web exposure models for river otters (*Lutra canadensis*).

<u>Assessment Endpoint 8</u> – Viability of finfishes utilizing the estuarine system.

This assessment endpoint was evaluated by five measurement endpoints: 1) comparisons of concentrations of COPC in surface water to general literature-based effects levels; 2) results of toxicity tests conducted with early (and sensitive) life stages of aquatic biota exposed to COPC in surface water; 3) HQs derived from residue-based toxicity reference values (TRVs) and finfish bioaccumulation models; 4) HQs derived from residue-based TRVs and finfishes collected onsite in Purvis Creek; and 5) evaluation of the benthic community as a food source for juvenile and adult fishes.

8.3.4 Ecological Exposure and Effects Evaluation

8.3.4.1 Overview

This portion of the OU1 BERA Report describes temporal trends of COPC in surface sediment of the estuary at the LCP Site between 2000 and 2007; the presence of chemicals in various environmental media of the LCP estuary; and describes the laboratory-, field-, and modeling-based analyses that form the basis for the risk characterization for benthic and aquatic invertebrates, fish, and wildlife receptors. These analyses are described briefly below.

8.3.4.2 Analytical Chemistry Results for Sediment, Surface Water, and Biota

The OU1 BERA Report presents data on the concentrations of COPC in surface water, sediment, and biota over the 2000 to 2007 monitoring period. Tables 4-1 through 4-12 of the OU1 BERA Report provide detailed summaries of these data. As described previously, the BERA Report concludes that there were no discernible temporal COPC concentration trends for sediment or biota in the LCP estuary over the extended monitoring period.

8.3.4.3 Surface Water Toxicity Tests

Chronic toxicity tests with surface water from the LCP estuary were conducted in 2000 and included eight replicate measurements of survival and growth in mysid shrimp (*Mysidopsis bahia*) and four replicate measurements of survival and growth in sheepshead minnows (*Coleonyx variegatus*) from four stations in the LCP estuary and two reference stations. For the mysids, the mean survival and growth was similar to the control and reference stations. For the sheepshead minnows, only the tests conducted with water collected from Station C-33 in Domain 3 had a mean growth rate that was statistically lower than the control and Crescent River reference station. Two out of the four replicates from this station also exhibited survival less than 80%, which is the minimum acceptable survival for control organisms. The results of the surface water toxicity tests are summarized in Tables 4-13 and 4-14 of the OU1 BERA Report.

8.3.4.4 Sediment Toxicity Tests with Laboratory-Cultured Invertebrates

Sediment toxicity tests with the amphipod (*Leptocheirus plumulosus*) were conducted during each monitoring event between 2000 and 2006. Measurement endpoints were survival, growth, and reproductive response. Table 4-14 of the OU1 BERA Report summarizes the results of the amphipod toxicity tests by year and Tables 4-15 through 4-19 summarize the results of the amphipod toxicity tests conducted in 2006, when the potential causes of sediment toxicity were evaluated by a comprehensive set of amphipod studies that included a Site-specific toxicity identification evaluation (TIE), equilibrium partitioning study for metals, and an AET study.

Sediment toxicity tests with the grass shrimp (*Palaemonetes pugio*) were conducted during each monitoring event between 2000 and 2005. Measurement endpoints included embryo development rate, embryo hatching rate, ovary maturation rate, survival, and DNA strand damage in embryos. Table 4-21 of the OU1 BERA Report summarizes the results of the grass shrimp toxicity tests by year.

Using all valid toxicity test data, a variety of Site-specific sediment effect concentrations (SEC) were calculated separately for each of the assessment endpoints for amphipods and grass shrimp based on common approaches presented in the scientific literature (Long and Morgan, 1990; MacDonald et al., 1996; Cubbage, et al., 1997). The SEC metrics included AETs, threshold effect levels (TELs), probable effects levels (PELs), effects range low (ER-L), and effects range medium (ER-M). These SECs, shown in Tables 4-20 and 4-22 of the OU1 BERA, provided a range of benchmarks to assess potential toxicity.

8.3.4.5 Sediment Toxicity Tests with Indigenous Grass Shrimp

Sediment samples from the LCP estuary were also evaluated in chronic toxicity tests using grass shrimp indigenous to the LCP estuary and Blythe Island. These tests were limited to two measurement endpoints (embryo hatching rate and DNA strand damage in embryos), and conducted during each monitoring event between 2002 and 2007. Statistically significant reductions in these measurement endpoints (as compared with reference sediments) were only observed in tests of sediment samples from the Main Canal, the bank of the Main Canal, and the Eastern Creek. The results of these studies are summarized in Table 4-24 of the OU1 BERA Report.

8.3.4.6 Studies of the Benthic Community

Field-based studies of the benthic community structure and function were limited. Benthic community surveys conducted at four stations in the LCP estuary during the 2000 monitoring event revealed reduced number of taxa, individual organisms, and density at two of the four Site stations as compared with two reference stations. These two stations were both in areas characterized by relatively high concentrations of COPC in the sediment. Polychaetes were the dominant species in the reference locations and Site stations. The results of this study are summarized in Table 4-25 of the OU1 BERA Report.

Fiddler crab abundance in the LCP estuary was sampled in a single-season study at a single location characterized by relatively high body burdens of COPCs (Black and Veatch, 2011). Sediment chemistry at the sampling station was not collected to evaluate fiddler crab exposure. Abundance of fiddler crabs at that single location was similar to that reported over 30 years ago at the relatively pristine Duplin Estuary Marsh in Georgia (Wolf et al., 1975).

8.3.4.7 Development of Hazard Quotients for Fish and Wildlife

Exposures of finfish to COPC and the potential for adverse effects as a result of those exposures were evaluated in the BERA using two different approaches. In the first approach, concentrations of COPC in finfish tissue (in units of mg/kg wet weight) via surface water and prey items, were calculated using models published in the scientific literature (Evans and Engle, 1994; Clark et al., 1990; Bergen et al., 1993; Gobas, 1993) and compared with tissue residue-based TRVs based on no observed adverse effects levels (NOAELs) and lowest observed adverse effect levels (LOAELs) to generate HQs. In the second approach, measured COPC concentrations in the tissue of finfish collected from the LCP estuary were compared with the

same tissue residue-based NOAEL and LOAEL TRVs to generate HQs. Using both approaches, HQs were developed for red drum, silver perch, black drum, spotted seatrout, and striped mullet.

The exposure assumptions and tissue residue-based TRVs used in the finfish exposure models are shown in Tables 4-26 and 4-27 of the OU1 BERA Report, respectively. The calculated HQs based on modeled and empirically-measured fish tissue concentrations are provided in Tables 4-28 and 4-29 of the OU1 BERA Report, respectively.

8.3.4.8 Development of Hazard Quotients for Wildlife

Exposures of wildlife receptors to COPC and the potential for adverse effects as a result of those exposures was evaluated in the BERA by calculating daily intakes of COPC (in units of mg/kg body weight/day) and comparing these calculated intakes with dietary TRVs based on NOAELs and LOAELs to generate HQs. Using this approach HQs were developed for diamondback terrapin, red-winged blackbird, clapper rail, green heron, marsh rabbit, raccoon, and river otter.

The exposure assumptions and dietary TRVs use in the wildlife exposure models are shown in Tables 4-26 and 4-27 of the OU1 BERA Report, respectively. The calculated HQs for wildlife receptors are provided in Table 4-30 of the OU1 BERA Report.

8.3.5 Risk Characterization for Assessment Endpoints

8.3.5.1 Overview

Risk characterization involves the integration of exposure and effects data to evaluate the likelihood of adverse effects. The BERA for the LCP estuary evaluates potential risk pertaining to eight assessment endpoints using one or more measurement endpoints to evaluate each of the assessment endpoints. The results associated with these measurement endpoints serve as lines of evidence (LOE) to support the risk characterization.

8.3.5.2 Benthic Estuarine Community (Assessment Endpoint 1)

Three basic measurement endpoints were employed to evaluate the viability of the structure and function of the benthic estuarine community in the LCP estuary. These endpoints were: 1) comparisons of concentrations of COPC in surface sediment with Site-specific effects levels; 2) results of toxicity tests conducted with sensitive life stages of benthic biota exposed to surface sediment; and 3) evaluation of the indigenous benthic community.

Concentrations of total mercury and Aroclor-1268 in creek and marsh surface sediment exceeded their Site-specific SECs in most segments of the Eastern Creek, the Main Canal, and Domain 1. Levels of lead in surface sediment exceeded the Site-specific ER-L of 60 mg/kg in portions of Domain 2 and in Domain 3. Total PAHs occurred in excess of their Site-specific survival ER-L of 1.5 mg/kg in the Eastern Creek, and in portions of Domains 2 and 3.

Potential causes of sediment toxicity were evaluated in 2006 by a comprehensive set of amphipod studies that included a Site-specific TIE study, an equilibrium partitioning study for metals, and an AET study. The AET study evaluated survival, growth, and/or reproduction of

lab-cultured amphipods exposed to surface sediment samples collected from 150 locations in the Eastern Creek, Main Canal, and Western Creek Complex. Endpoints were often significantly reduced relative to controls and some reference areas. The OU1 BERA Report concluded that the observed toxicity appeared to be caused by COPC, and to a limited extent from other metals, but also acknowledged that there were no discernible COPC exposure-response relationships of high predictive value and toxicity was substantially influenced by other factors including TOC, sulfide, and grain size.

Sediment toxicity test results with lab-cultured grass shrimp suggest that grass shrimp may be more sensitive than amphipods. For example, reproductive TELs for embryo development and hatching success from exposure to mercury in sediments ranged from 1.4 to 3.9 mg/kg, while the reproductive TEL for amphipods exposed to mercury was 4.9 mg/kg.

Hatching success and DNA strand damage of embryos produced from indigenous grass shrimp throughout the 2002-2007 study period deviated statistically (and adversely) from control conditions in the Main Canal, the bank of the Main Canal, and the Eastern Creek. An evaluation of the indigenous benthic community in the LCP estuary suggested a hazard less than that predicted by laboratory-based studies. In a single field evaluation conducted in 2000, the differences in metrics of the macrobenthos community between Site and reference areas included a lesser number of taxa, individuals, and density of individuals at two of the four Site stations. These stations included C5 (at the mouth of the main canal) and C33 (at the marsh/upland border in Domain 3). The stations in Purvis Creek and Eastern Creek were within the range seen in reference areas for total taxa and above the range seen in the reference areas for total individuals and mean density, as enumerated on Table 4-25 of the BERA. Dominance by polychaetes was characteristic of all Site and reference stations.

The OU1 BERA Report concluded that these LOE for collectively evaluating the viability of the structure and function of the benthic estuarine community in the LCP estuary indicate that the potential for risk associated with COPC and unidentified non-COPC is evident, particularly in the Main Canal and Eastern Creek.

8.3.5.3 Omnivorous Reptiles (Assessment Endpoint 2)

One LOE was used to evaluate the viability of omnivorous reptilian species utilizing the LCP marsh: HQs derived from food-web exposure models for diamondback terrapins. Because all HQs derived for diamondback terrapins were substantially below 1, the OU1 BERA Report concluded that there is no potential risk to the viability of omnivorous reptiles utilizing the LCP estuary.

8.3.5.4 Omnivorous Birds (Assessment Endpoint 3)

The two LOE used to evaluate the viability of omnivorous avian species utilizing the LCP estuary were: 1) HQs derived from food-web exposure models for red-winged blackbirds; and 2) HQs derived from food-web exposure models for clapper rails. The following is a summary of the findings:

- All food-web HQs (NOAEL and LOAEL) for inorganic mercury, Aroclor-1268, and lead were all below 1 for both red-winged blackbirds and clapper rails, indicating no potential for risk.
- For red-winged blackbirds, modeled NOAEL and LOAEL HQs for MeHg were at or below 1 in all domains.
- For clapper rails modeled for exposure to MeHg all LOAEL HQs were less than 1. NOAEL HQs were slightly greater than 1 in Domain 1 (3.0), Eastern Creek (2.6), and the Main Canal (1.7).

Based on these findings, the OU1 BERA Report concluded that the overall potential for risk to omnivorous birds in the LCP estuary is minimal.

8.3.5.5 Piscivorous Birds (Assessment Endpoint 4)

One LOE was used to evaluate the viability of piscivorous avian species utilizing the LCP estuary: HQs derived from food-web exposure models for green herons. The following is a summary of the findings:

- All food-web HQs (NOAEL and LOAEL) for inorganic mercury, Aroclor-1268, and lead were below 1 for green herons, indicating no potential for risk.
- All NOAEL HQs generated by the green heron modeled for exposure to MeHg exceeded 1 (1.4 to 10.6).
- LOAEL HQs for green herons modeled for MeHg exposure at the Site exceeded 1 in Domain 1 (2.8), Eastern Creek (3.5), and the Main Canal (1.5).

Based on these findings, the OU1 BERA Report concluded that potential risk to the viability of piscivorous avian species in the LCP estuary is moderate.

8.3.5.6 Herbivorous Mammals (Assessment Endpoint 5)

One LOE was used to evaluate the viability of herbivorous mammalian species utilizing the LCP marsh: HQs derived from food-web exposure models for marsh rabbits. The following is a summary of the findings:

- All NOAEL and LOAEL HQs for inorganic mercury, MeHg, and lead were below 1 for marsh rabbits, indicating no potential for risk.
- For marsh rabbits modeled for exposure to Aroclor-1268 (based on a TRV for Aroclor 1254), all LOAEL HQs were less than 1. The NOAEL HQ was slightly greater than 1 in Domain 1 (3.0).

Based on these findings, the OU1 BERA Report concluded the potential for risk to herbivorous mammals foraging within the LCP estuary is minimal.

8.3.5.7 Omnivorous Mammals (Assessment Endpoint 6)

One LOE was used to evaluate the viability of omnivorous mammals foraging within the LCP estuary: HQs derived from food-web exposure models for raccoons. The following is a summary of the findings:

- All NOAEL and LOAEL HQs for inorganic mercury, MeHg, and lead, were below 1 for raccoons, indicating no potential for risk.
- For raccoons modeled for exposure to Aroclor-1268 (based on a TRV for Aroclor 1254), all LOAEL HQs were less than 1. NOAEL HQs were slightly greater than 1 in Domain 1 (2.6) and Domain 2 (1.1).

Based on these findings, the BERA Report concluded that the potential for risk to the viability of omnivorous mammals utilizing the LCP estuary is minimal.

8.3.5.8 Piscivorous Mammals (Assessment Endpoint 7)

One LOE was used to evaluate the viability of piscivorous mammals foraging within the LCP estuary: HQs derived from food-web exposure models for river otters. The following is a summary of the findings:

 The modeling study for river otters generated Site NOAEL HQs for Aroclor-1268 (based on a TRV for Aroclor 1254) that ranged from 0.1 to 3.9. No LOAEL-based HQ for Aroclor-1268 exceeded 1. In addition, no risk of adverse effects was predicted for mercury or lead exposures.

Based on these findings, the BERA Report concluded that the potential risk to the viability of piscivorous mammalian species utilizing the LCP estuary is minimal.

8.3.5.9 Finfish (Assessment Endpoint 8)

Five LOEs were used to evaluate the viability of finfish inhabiting the LCP estuary: 1) comparisons of concentrations of COPC in surface water to general literature-based effects levels; 2) results of toxicity tests conducted with sensitive life stages of aquatic biota exposed to COPC in surface water; 3) HQs derived from food-web exposure models for upper trophic-level fish; 4) HQs derived from measured residues in field-collected fish; and 5) evaluation of the benthic macroinvertebrate community (as a food source for juvenile and adult fishes).

- The highest concentration of total mercury measured in surface water of the LCP estuary (188 nanograms per liter (ng/L) in the Eastern Creek in 2000) is less than the CCC of 940 ng/L. The highest concentration of dissolved lead in water (2.5 µg/L in the Main Canal during 2000), is below the CCC of 8.1 µg/L. No criteria have been developed specifically for Aroclor-1268.
- Laboratory toxicity tests designed to evaluate chronic toxicity of "whole" surface water from the LCP estuary to mysid shrimp and sheepshead minnows generated similar results. Mean survival of mysids exposed to surface water from the LCP estuary and two reference locations ranged from 92.4 to 100%, which was greater than the minimum

acceptable survival for control organisms (80%). Mean growth (measured as weight) of mysids exposed to surface water from the Site and from reference locations exceeded the weight of control organisms. Survival of sheepshead minnows exposed to the same surface water ranged from 80 to 100%, which was at least equal to the minimum acceptable survival for control organisms (80%). Mean growth of fish exposed to Site surface water was statistically similar to weight observed for at least one reference location.

- The mean LOAEL HQ derived using a fish bioaccumulation model for MeHg was 2.9. Using three different fish bioaccumulation models for PCBs, mean LOAEL HQ values for Aroclor-1268 ranged from 0.5 to 1.4. The modeled tissue concentrations on which these HQs are based are generally higher than the measured concentrations in most species of fish collected from the LCP estuary.
- When HQs were derived based on measured concentrations in field-caught fish from the LCP estuary, mean LOAEL HQs for MeHg slightly exceeded 1 in silver perch (1.3), black drum (1.1) and spotted seatrout (1.9). Mean LOAEL HQs for Aroclor-1268 slightly exceeded 1 in silver perch (1.1), black drum (1.1), and stripped mullet (2.5).
- Evaluation of the benthic macroinvertebrate community in the LCP estuary did not identify a limitation of this source of food to fishes, although toxicity to benthic organisms may limit food for fish in portions of the Main Canal, Eastern Creek, and Western Creek Complex.

Based on an overall evaluation of these five measurement endpoints, the OU1 BERA concluded that that there is no risk to fish in the LCP estuary from direct exposure to COPC in the water column. However, the bioaccumulation modeling and field data for finfish suggest that chronic risk to viability of finfish indigenous to the LCP estuary is of concern.

8.3.6 Ecological Sediment Remedial Goal Options

The OU1 BERA Report concluded that potential ecological risks from hazardous substances released to the LCP estuary warrant an evaluation of actions that would reduce the incidence of adverse growth and reproductive effects to benthic organisms, fish, and wildlife. The OU1 BERA Report provides the following list of receptor groups considered to be at potential risk:

- Benthic invertebrates from MeHg, Aroclor-1268, lead, and PAHs;
- Fish from MeHg and Aroclor-1268;
- Omnivorous and piscivorous birds from MeHg; and
- Herbivorous, omnivorous, and piscivorous mammals from Aroclor-1268.

Note, however, that this list includes receptor groups for which the *Risk Characterization* section of the OU1 BERA Report concludes that risks are "minimal". These include omnivorous birds, herbivorous mammals, omnivorous mammals, and piscivorous mammals.

EPA used the food-web exposure models and TRVs to "back-calculate" sediment COPC concentrations considered protective for each receptor (also called RGOs). This process required

the development of sediment-to-biota bioaccumulation factors (BAFs), which are measurements of COPC in biota tissue divided by the sediment COPC concentrations. Several different methods were used to derive BAFs for finfish as well as the various prey items evaluated in the wildlife food-web models. In general, these methods attempted to account for the spatial variability in sediment concentrations potentially contributing to the body burden measurements in finfish and prey items. The methodologies used to derive RGOs for each receptor are described in detail in Section 7 of the BERA Report. The RGOs based on NOAEL and LOAEL toxicity endpoints for each receptor were used in a "Rule of 5" approach that creates a matrix of potential RGOs for consideration in the FS. The application and use of RGOs will be discussed in the FS, including consideration of localized areas of potential risk for individual organisms, risk reduction for the ecological receptors that use the estuary, and overall protectiveness of populations and communities provided by the selected remedy.

8.3.7 Uncertainty Analysis

The OU1 BERA Report examines a variety of uncertainties associated with the components of the BERA process and considers whether these uncertainties tend to over- or underestimate risks. It also presents findings from several "independent studies" conducted in the LCP estuary and evaluates whether those studies lend additional support to, or conflict with, the conclusions of the BERA. The most significant sources of uncertainty in the OU1 BERA are briefly described in the following bullets. It is the belief of the PRPs that application of conservative assumptions and interpretations to each of these sources of uncertainty generally results in an overestimation of risks for the assessment endpoints evaluated in the BERA.

- The evaluation of potential adverse effects to the benthic invertebrate community relied on hundreds of Site-specific toxicity test measurements using both indigenous and laboratory-cultured organisms. The results of these tests suggest that Site COPC can contribute to chronic toxicity of benthic invertebrates at high COPC concentrations, but toxicological responses observed at low COPC concentrations also suggest the influence of other unknown factors. As such, the OU1 BERA Report notes that the development of RGOs for the protection of benthic invertebrates is "highly uncertain with poor accuracies" and that "only conservative assumptions were used" for this purpose.
- The evaluation of potential adverse effects to mammalian receptors from Aroclor-1268 is based on a TRV for Aroclor-1254. Appendix J of the OU1 BERA Report contains a detailed discussion of the relative toxicities of these two PCB mixtures and concludes that the use of the Aroclor-1254 TRV to represent the toxicity of Aroclor-1268 overestimates the potential for adverse effects to the mammalian assessment endpoints considered in the OU1 BERA.
- The evaluation of potential adverse effects to upper-trophic level fish from Aroclor-1268 is based on a tissue residue TRV derived though an extremely conservative interpretation of a toxicity study for that PCB mixture by EPA. This TRV is based on a study published by Matta et al. (2001), in which a statistically significant growth increase was

- observed in mummichogs with a measured tissue level of 1.3 mg/kg (wet weight) Aroclor-1268. EPA determined that this concentration represented an LOAEL rather than NOAEL, resulting in an overestimation of the potential for adverse effects to this assessment endpoint.
- The evaluation of potential adverse effects to upper trophic-level fish, birds, and mammals is based the calculation of HQs. While this has become routine in the realm of regulatory risk assessment, the practice has been criticized by Tannenbaum (2005, 2007) and others. The HQ is simply the ratio of a conservative exposure estimate and a conservative TRV, and is not a measure of the probability that an adverse effect will occur. Furthermore, the HQ relates to the response of an individual organism, rather than the population. Use of the HQ methodology involves the implicit assumption that as exposures and HQs increase, an increasing number of individuals could experience adverse effects, and that the higher the number of individuals affected, the greater the risk to the population. In reality, density-dependent biological processes, such as competition for limited food resources, can offset reductions in the reproductive output of individual organisms. In addition, it is well documented that wildlife can acclimate and adapt to elevated levels of chemicals in the environment, thereby mitigating adverse population-level effects.

Page 2 of 2 Created August 2012

Table 7-1
Identification and Resolution of Historical Upland Sources

Upland Source	Related Process	Route of Entry	Description of Potential Source	Resolution
API Separators	Crude Oil Refinery	Stormwater Sewers	Stormwater (and perhaps sanitary sewer from ARCO community) was historically directed into the two large API Separators. API Separators may have served additional function during the refinery operations. COCs included Pb, PAHs, and PCBs (south separator).	The API Separators were dug out, residuals were stabilized, and the area was backfilled.
Outfall Canal and Pond	Paint Manufacturing, Chloralkali Plant	Process Sewers	The process sewers were directed to the marsh via two pipelines, to the head of the Outfall Canal and to the Outfall Pond. The Outfall Pond served as a solids settling basin where water was discharged to LCP Ditch over a weir. At high tide, estuarine waters "pushed" the sewer discharge back up LCP Ditch. COCs included Hg and PCBs.	All outfalls were closed. The Outfall Pond was excavated and backfilled.
Brine Mud Impoundments	Chloralkali Plant	Process Sewers	The Brine Mud Impoundments were created ca. 1970.	The impoundments were excavated and backfilled.
Mercury Cell Buildings	Chloralkali Plant	Process Sewers	The mercury cells were used to produce the bleach, soda, gas, and acid by the electrolysis of sodium chloride.	The two mercury cell buildings were demolished and the concrete slab was capped to prevent future mercury emissions. The cap was planted with a Bermuda grass surface that is routinely mowed.
Former Facility Disposal Area (FFDA)	Paint Manufacturing, Chloralkali Plant	Overland Runoff	Located in the southwest portion of site. FFDA was created ca. 1951. The FFDA was routinely inundated by high tides causing scouring into nearby marsh. COCs included PCBs, Hg, and Pb.	The FFDA was excavated and backfilled.
Bunker C Oil Tanks	Power Generation	Overland Runoff	Located in the central portion of the site.	The Bunker C Oil tanks were removed and underlying soils were remediated.
Erosion	Natural Processes	Overland Runoff	General overland runoff throughout site.	Site grading, boundary restoration

COC: chemical of concern

PAH: polycyclic aromatic hydrocarbon

Pb: lead

PCB: polychlorinated biphenyl

Table 8-2 Experimental Design of the BERA

Measurement ^a	Number of sampling stations ^{b, c}	Analytical method ^d	Typical detection limit	Other details
	3	Metals: usually 6020A; Aroclors: 8082; Total PAHs: 8270-SIM	Various	<u>Toxicity Identification Evaluation (TIE)</u> Analytical methods pertain to pore water analyses
Grass shrimp	9	Special Lee test		Direct evaluation of reproduction and DNA strand damage (Comet Test) of shrimp collected in field (no laboratory exposure to sediment)
		Benthic Com	munity Creek Surfa	ace Sediment
Benthic macro- invertebrates	6 (2000)	Relative numerical abundance		Evaluation of number of taxa, taxonomic groups, and individuals; density of individuals; diversity and equitability indices
	Biota Collected	for Evaluation of Che	mical Body Burdens	(Residue) Creek and Marsh Stations
Cordgrass (2005)	20			1 replicate (>100 g) per sampling station collected above 15 cm from ground
Eastern oysters	8			3 replicates of about 100 composited young-of-year (Year 0) oysters and 20 composited older (Years I and II) oysters per sampling station
Fiddler crabs	15			4 - 7 replicates of about 15 - 50 composited crabs (mostly males) per sampling station; replicate weight = about 16 - 55 g
Grass shrimp	9			3 replicates of about 50 composited shrimp per sampling station
Blue crabs	3			7 replicates of individual male crabs per sampling station; crab length (point-to-point on carapace) = about 130 - 170 mm (155 - 352 g)
Mummichogs	13			1 to 3 replicates of 5 - 30 composited fish (about 45 - 100 mm in length) per sampling station; replicate weight = 18.4 - 59.6 g
Silver perch	2			8 replicates of individual silver perch per sampling station; fish length (total length) = 155 - 185 mm (50 - 89 g)
Red drum	1			3 replicates of individual red drum at sampling station; fish length (total length) = 355 - 415 mm (527 - 832 g)
Black drum	2			8 replicates of individual black drum per sampling station; fish length (total length) = 170 - 220 mm (87- 158 g)
Spotted seatrout	2			8 replicates of individual spotted seatrout per sampling station; fish length (total length) = 290 - 390 mm (236 - 627 g)
Striped mullet	2			5 - 8 replicates of individual striped mullet per sampling station; fish length (total length) = 230 - 340 mm (177 - 497 g)
	Chem	nical (Residue) Analys	es Performed on Biot	a (Whole Bodies Analyzed)
Total mercury		1631E	0.0001 mg/kg (wet wt)	
Methylmercury (2005)		1630 (mod)	0.0004 mg/kg (wet wt)	
Aroclor 1268		8082	0.0006 mg/kg (wet wt)	
Lead		6020	0.001 mg/kg (wet wt)	
Lipids		NOAA NOS ORCA 71	0.05% (wet wt)	Evaluated in just blue crabs and large finfishes (not reported).

^aAll measurements (studies) were performed in 2006 except those identified as occurring in 2000 or 2005.

^bNumber of sampling stations includes reference locations -- Crescent River and/or Troup Creek.

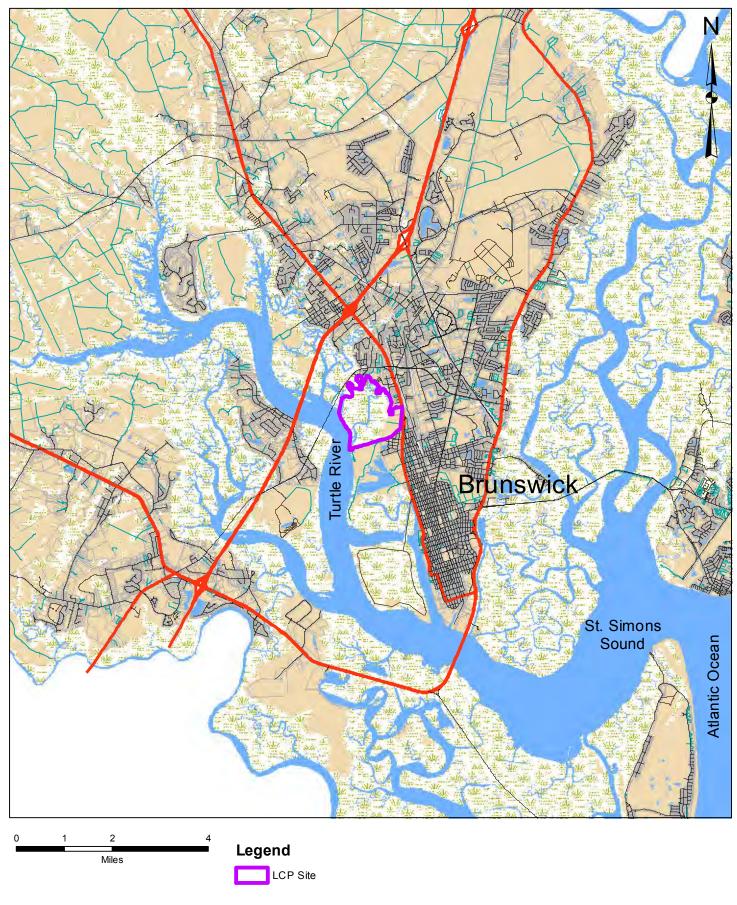

^cThe 150 creek sediment samples are associated exclusively with the AET study conducted during this investigation. Evaluation of sediment for secondary metals, SEM, and AVS was performed on just those sediment samples also tested for toxicity in the main amphipod study.

^dAnalytical methods are U. S. EPA methods unless otherwise indicated.

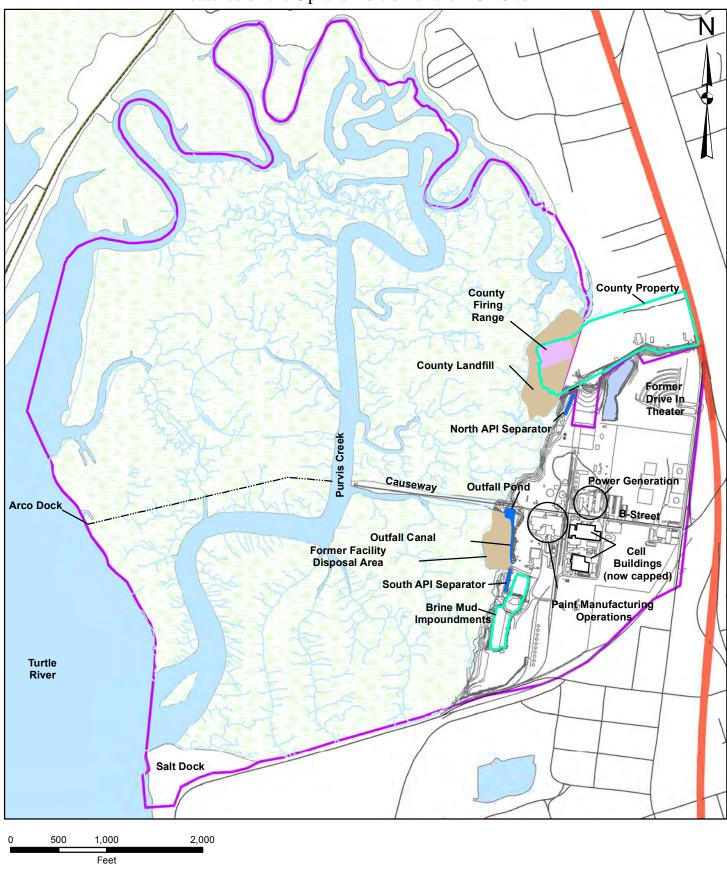

^eSurface sediment is defined as between 0 and 15 cm in depth.
