DOCUMENTATION OF ENVIRONMENTAL INDICATOR DETERMINATION

Interim Final 2/5/99

RCRA Corrective Action

Environmental Indicator (EI) RCRIS code (CA750) Migration of Contaminated Groundwater Under Control

Facility Name:	Bettis Atomic Power Laboratory
Facility Address:	P.O. Box 109, West Mifflin, PA 15122
Facility EPA ID #:	PA0 89 009 0004
groundwater me	e relevant/significant information on known and reasonably suspected releases to the dia, subject to RCRA Corrective Action (e.g., from Solid Waste Management Units lated Units (RU), and Areas of Concern (AOC)), been considered in this EI determination?
<u>X</u>	If yes - check here and continue with #2 below.
	If no - re-evaluate existing data, or
	If data are not available skip to #6 and enter"IN" (more information needed) status code
BACKGROUND	

<u>Definition of Environmental Indicators (for the RCRA Corrective Action)</u>

Environmental Indicators (EI) are measures being used by the RCRA Corrective Action program to go beyond programmatic activity measures (e.g., reports received and approved, etc.) to track changes in the quality of the environment. The two EI developed to-date indicate the quality of the environment in relation to current human exposures to contamination and the migration of contaminated groundwater. An EI for non-human (ecological) receptors is intended to be developed in the future.

<u>Definition of "Migration of Contaminated Groundwater Under Control" EI</u>

A positive "Migration of Contaminated Groundwater Under Control" EI determination ("YE" status code) indicates that the migration of "contaminated" groundwater has stabilized, and that monitoring will be conducted to confirm that contaminated groundwater remains within the original "area of contaminated groundwater" (for all groundwater "contamination" subject to RCRA corrective action at or from the identified facility (i.e., site-wide)).

Relationship of EI to Final Remedies

While Final remedies remain the long-term objective of the RCRA Corrective Action program the EI are near-term objectives which are currently being used as Program measures for the Government Performance and Results Act of 1993, GPRA). The "Migration of Contaminated Groundwater Under Control" EI pertains ONLY to the physical migration (i.e., further spread) of contaminated ground water and contaminants within groundwater (e.g., nonaqueous phase liquids or NAPLs). Achieving this EI does not substitute for achieving other stabilization or final remedy requirements and expectations associated with sources of contamination and the need to restore, wherever practicable, contaminated groundwater to be suitable for its designated current and future uses.

Duration / Applicability of EI Determinations

EI Determinations status codes should remain in RCRIS national database ONLY as long as they remain true (i.e., RCRIS status codes must be changed when the regulatory authorities become aware of contrary information).

Page 2

2.	Is groundwater known or reasonably suspected to be "contaminated" ¹ above appropriately protective "levels" (i.e., applicable promulgated standards, as well as other appropriate standards, guidelines, guidance, or criteria) from releases subject to RCRA Corrective Action, anywhere at, or from, the facility		
	<u>X</u>	If yes - continue after identifying key contaminants, citing appropriate "levels," and referencing supporting documentation.	
		If no - skip to #8 and enter "YE" status code, after citing appropriate "levels," and referencing supporting documentation to demonstrate that groundwater is not "contaminated."	
		If unknown - skip to #8 and enter "IN" status code.	

Rationale and Reference(s): A RCRA Facility Investigation (RFI) for the facility included a groundwater investigation which found that levels of tetrachloroethylene (PCE), trichloroethylene (TCE), and dichloroethylene (DCE) in groundwater and attributable to the facility exceeded EPA Region III's Risk Based Concentrations (RBCs) for these substances in groundwater and thus may potentially present an unacceptable risk.

References:

- 1) Final RFI Report for the Bettis Laboratory, June 1994; and,
- 2) EPA Letter (Z. Maldonado) to Pittsburgh Naval Reactors Office (J.Sage) dated August 2, 1994 approving Final RFI Report for the Bettis Laboratory.

Footnotes:

¹"Contamination" and "contaminated" describes media containing contaminants (in any form, NAPL and/or dissolved, vapors, or solids, that are subject to RCRA) in concentrations in excess of appropriate "levels" (appropriate for the protection of the groundwater resource and its beneficial uses).

Page 3

Has the **migration** of contaminated groundwater **stabilized** (such that contaminated groundwater is

•	expected to remain within "existing area of contaminated groundwater" as defined by the monitoring ocations designated at the time of this determination)?	
<u>X</u>	If yes - continue, after presenting or referencing the physical evidence (e.g., groundwater	

3.

groundwater is expected to remain within the (horizontal or vertical) dimensions of the "existing area of groundwater contamination" ²).
 If no (contaminated groundwater is observed or expected to migrate beyond the designated locations defining the "existing area of groundwater contamination" ²) - skip to #8 and enter "NO" status code, after providing an explanation.
If unknown - skip to #8 and enter "IN" status code.

Rationale and Reference(s): The Final RFI identifies five water bearing zones underlying the facility. The deepest identified water bearing zone was the Pittsburgh Coal zone. The Final RFI found that groundwater at the facility flows predominantly vertically to the Pittsburgh Coal Zone. Groundwater which flows laterally was found to either be contained within the facility property by rising groundwater elevations of the neighboring properties, to discharge to surface water (see #4 and #5 below) or, in one case, to migrate to a neighboring property. RFI investigations found that groundwater in the Pittsburgh Coal Zone did not contain detectable levels of facility-related contaminants and that groundwater migrating to the neighboring property was discharging to the ground surface via seeps and/or springs. (Note: The risk assessment in the Final RFI found that the risk presented by these seeps/springs were within the acceptable risk range.) Groundwater monitoring points were established during the Final RFI to monitor the extent of contaminated groundwater and monitoring of these points during the RFI indicated that contaminated groundwater was expected to remain within the existing area of contaminated groundwater.

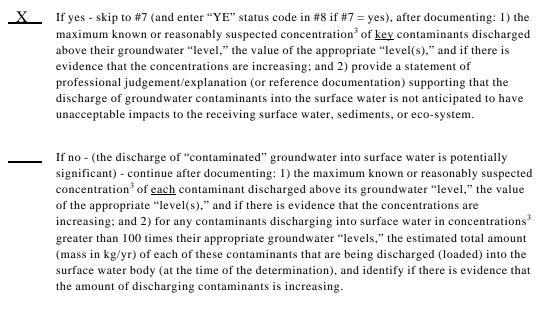

² "existing area of contaminated groundwater" is an area (with horizontal and vertical dimensions) that has been verifiably demonstrated to contain all relevant groundwater contamination for this determination, and is defined by designated (monitoring) locations proximate to the outer perimeter of "contamination" that can and will be sampled/tested in the future to physically verify that all "contaminated" groundwater remains within this area, and that the further migration of "contaminated" groundwater is not occurring. Reasonable allowances in the proximity of the monitoring locations are permissible to incorporate formal remedy decisions (i.e., including public participation) allowing a limited area for natural attenuation.

4. Does "contaminated" groundwater discharge into surface water bodies?		
	<u>X</u>	If yes - continue after identifying potentially affected surface water bodies.
		If no - skip to #7 (and enter a "YE" status code in #8, if #7 = yes) after providing an explanation and/or referencing documentation supporting that groundwater "contamination" does not enter surface water bodies.
		If unknown - skip to #8 and enter "IN" status code.
4. 6. 4		eference(s): Based on the Final RFI, contaminated groundwater from the facility appear

rs to be discharging to surface water. The subject receiving stream is Bull Run.

Page 5

5. Is the **discharge** of "contaminated" groundwater into surface water likely to be "**insignificant**" (i.e., the maximum concentration³ of each contaminant discharging into surface water is less than 10 times their appropriate groundwater "level," and there are no other conditions (e.g., the nature, and number, of discharging contaminants, or environmental setting), which significantly increase the potential for unacceptable impacts to surface water, sediments, or eco-systems at these concentrations)?

If unknown - enter "IN" status code in #8.

Rationale and Reference(s): Surface water samples collected during the RFI found PCE, TCE and DCE to be present at low concentrations in Bull Run. The maximum detected concentrations of these compounds were 53 ug/l, 5 ug/l and 4 ug/l, respectively. The Final RFI concluded that the subject levels did not present a significant health threat. However, to help ensure that VOC levels did not increase and potentially present an unacceptable risk in the future, corrective measures for the facility (see Final Decision and Response to Comments for the Bettis facility dated August 15, 1997) included the collection and treatment of subsurface drainage adjacent to Bull Run and surface water monitoring of Bull Run. The subject collection/treatment system is in operation (see letter from Bettis to EPA dated 2/13/01) and has been approved by EPA (see letter from EPA to Bettis dated 3/6/01). In addition, Bettis is monitoring surface water in Bull Run and sample results for 2000 and 2001 (see 2000 and 2001 Environmental Monitoring Reports for Bettis prepared by Bechtel Bettis Inc.) indicate no increase in VOC concentrations in Bull Run surface water.

³ As measured in groundwater prior to entry to the groundwater-surface water/sediment interaction (e.g., hyporheic) zone.

Page 6

6.	Can the discharge of "contaminated" groundwater into surface water be shown to be " currently acceptable" (i.e., not cause impacts to surface water, sediments or eco-systems that should not be allowed to continue until a final remedy decision can be made and implemented ⁴)?	
		If yes - continue after either: 1) identifying the Final Remedy decision incorporating these conditions, or other site-specific criteria (developed for the protection of the site's surface water, sediments, and eco-systems), and referencing supporting documentation demonstrating that these criteria are not exceeded by the discharging groundwater; OR 2) providing or referencing an interim-assessment, ⁵ appropriate to the potential for impact, that shows the discharge of groundwater contaminants into the surface water is (in the opinion of a trained specialists, including ecologist) adequately protective of receiving surface water, sediments, and eco-systems, until such time when a full assessment and final remedy decision can be made. Factors which should be considered in the interim-assessment (where appropriate to help identify the impact associated with discharging groundwater) include: surface water body size, flow, use/classification/habitats and contaminant loading limits, other sources of surface water/sediment contamination, surface water and sediment sample results and comparisons to available and appropriate surface water and sediment "levels," as well as any other factors, such as effects on ecological receptors (e.g., via bio-assays/benthic surveys or site-specific ecological Risk Assessments), that the overseeing regulatory agency would deem appropriate for making the EI determination.
	_	If no - (the discharge of "contaminated" groundwater can not be shown to be "currently acceptable") - skip to #8 and enter "NO" status code, after documenting the currently unacceptable impacts to the surface water body, sediments, and/or eco-systems.
		If unknown - skip to 8 and enter "IN" status code.

Rationale and Reference(s):

⁴ Note, because areas of inflowing groundwater can be critical habitats (e.g., nurseries or thermal refugia) for many species, appropriate specialist (e.g., ecologist) should be included in management decisions that could eliminate these areas by significantly altering or reversing groundwater flow pathways near surface water bodies.

⁵ The understanding of the impacts of contaminated groundwater discharges into surface water bodies is a rapidly developing field and reviewers are encouraged to look to the latest guidance for the appropriate methods and scale of demonstration to be reasonably certain that discharges are not causing currently unacceptable impacts to the surface waters, sediments or eco-systems.

Page 7

7.	Will groundwater monitoring / measurement data (and surface water/sediment/ecological data, as necessary) be collected in the future to verify that contaminated groundwater has remained within the horizontal (or vertical, as necessary) dimensions of the "existing area of contaminated groundwater?"	
	<u>X</u>	If yes - continue after providing or citing documentation for planned activities or future sampling/measurement events. Specifically identify the well/measurement locations which will be tested in the future to verify the expectation (identified in #3) that groundwater contamination will not be migrating horizontally (or vertically, as necessary) beyond the "existing area of groundwater contamination."
		If no - enter "NO" status code in #8.
		If unknown - enter "IN" status code in #8.

Rationale and Reference(s): Per the Final Decision and Response to Comments for Bettis (dated 8/15/97), corrective measures to be implemented at Bettis include groundwater and surface water monitoring. The monitoring is being implemented and the results of monitoring to date indicate that groundwater is not migrating beyond the existing area of contamination (see 2000 and 2001 Environmental Monitoring Reports for Bettis prepared by Bechtel Bettis Inc.) .
