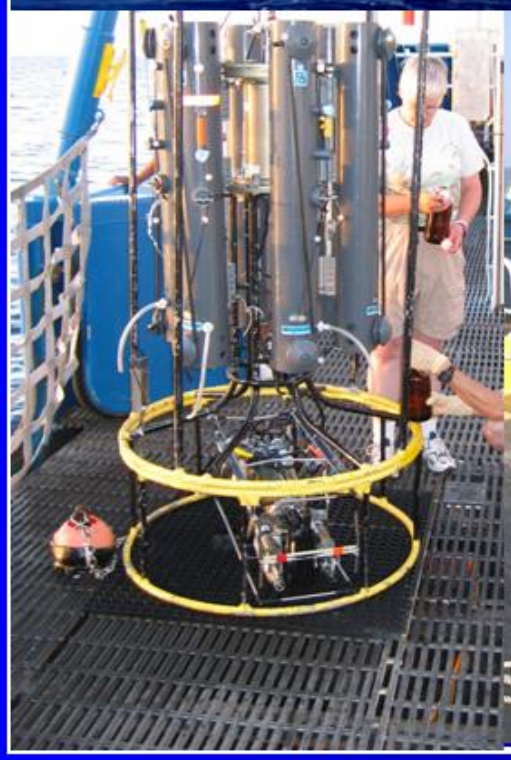
Brunswick ODMDS Status and Trends
May 2006



THIS PAGE INTENTIONALLY LEFT BLANK

ACKNOWLEDGEMENTS

Samples were collected May 7-8, 2006 from the Brunswick Ocean Dredged Material Disposal Site (Doug Johnson, Site Manager; Gary W. Collins, Chief Scientist). Sample tracking and custody were performed by Phyllis Meyer. Water quality profiling and sampling were led by Christopher McArthur. Sediment sampling was led by Steve Blackburn. On-board sample processing of the invertebrate samples, chemical samples, and the sediment particle size samples were led by Doug Johnson, Jennifer Derby and Kris Carter, respectively.

In addition, the scientific party would like to express their appreciation to the following members of senior-level management for taking the time out of their hectic schedules to allow us the opportunity to demonstrate the capabilities of the OSV Bold, along with our ocean protection monitoring techniques: Regional Administrator J.I. Palmer, Jr., Chief of Staff Don Christy, Water Division Director James Giattina, and WCNS Branch Chief Tom Welborn.

INTRODUCTION

Ocean disposal of dredged materials can affect the environment of a disposal site by disturbing the benthic community and potentially causing long-term reduction of oxygen in the pore waters of the sediments and the overlying waters. Natural oceanographic processes can also be responsible for transporting disposed materials offsite into nearby habitats.

As part of Region 4's strategy to monitor the effects of dredged material disposal within the marine environment, routine surveys of the benthos and water column within and adjacent to our sites are conducted so that their status may be assessed. In addition, the data is archived so that over time, trends which may occur can be observed. These status and trends surveys are consistent with the requirements of 40 C.F.R. 228.9. The present study being discussed was conducted aboard the Ocean Survey Vessel (OSV) Bold, May 7-8, 2006.

BACKGROUND

The Brunswick ODMDS was designated by EPA in 1989. The ODMDS receives an average of over 900,000 cubic yards of dredged material annually from the Brunswick Harbor Navigation Project. Project sediments typically range from 2 to 72 percent fine-grained material.

A Site Management and Monitoring Plan was developed for the Brunswick ODMDS in 1999. Annual bathymetry surveys have been conducted at the site by the Corps of Engineers. The last status and trends survey conducted at this ODMDS was in July 1995.

Survey Area and Location

The study area is within and surrounding the Brunswick, GA ODMDS located offshore Jekyll Island. The survey area is approximately 2 square nautical miles (nmi). Twelve stations were selected in order to analyze the sediment grain size, chemical, and biological characteristics of two areas – one where disposal has occurred and the other one undisturbed by disposal. Of these 12, one received water quality sampling. Depths in this area average approximately 30 feet. The ODMDS boundary corner coordinates are:

31°02'35"N 81°17'40"W
31°02'35"N 81°16'30"W
31°00'30"N 81°16'30"W
31°00'30"N 81°17'42"W

The ODMDS, survey area and station locations are shown in Figure 1.

METHODS AND MATERIALS

Method Rationale: Characterization of the benthic community and sediment size/chemistry at selected stations, followed by analysis of community parameters via statistical treatment, allows for identification and interpretation of changes in the community structure. Such community statistics can be used to draw inferences regarding perturbations to the benthic macroinvertebrate community and subsequently allow for judgments regarding the likelihood of impact from dredged material disposal.

Sampling Stations

The boundaries of the Brunswick ODMDS measure approximately 1 X 2 nmi. Twelve stations (see Table 1 and Figure 1) were established by selecting half within and half outside of the site. Station locations were selected in a stratified, random manner.

Water Quality

To characterize the general water quality associated with the dump site, the following water column parameters were sampled: conductivity, dissolved oxygen (DO), salinity, temperature, density, turbidity, % light transmission and Chlorophyll a.

All measurements were accomplished utilizing the OSV Bold's CTD. At the surface and bottom, Go Flow® bottles attached to the CTD/rosette frame were deployed to obtain grab samples for the laboratory analysis. Once the rosette was back aboard the ship, the bottles were emptied directly into the appropriate sample containers, labeled, and refrigerated until demobilization. Laboratory analysis of the water includes nutrients, metals, PAHs, PCBs and pesticides. In addition, one other sample container was filled with bottom water and analyzed for dioxins.

Seafloor Sampling

Bottom sampling at all twelve stations was accomplished by a minimum of two deployments of a Young grab (surface area = 0.04 m^2; depth of 10 cm) from the stern of the ship. After retrieval of the grab and confirmation of an adequate sample, the device was either sub-sampled in order to obtain discrete samples for sediment particle size analyses and sediment chemical analyses, or used entirely for benthic macroinvertebrate identification. The sampling device and handling/preservative protocol for each type of sample follows below:

Sediment Particle Size

Two separate samples for particle size were collected from the Young grab by acrylic 5 cm diameter coring tubes. The subsamples were placed into whirl packs, labeled, and frozen for return to the lab. The samples were analyzed at the Science and Ecosystem Support Division (SESD) laboratory by laser defraction (USEPA, 2001a). In addition, SESD provided data from all stations by wet sieving the fraction of the sample larger than 2 mm (USEPA, 2001b). The results of the laser analyses were converted from '% volume' to 'wet weight.'

Sediment Chemistry

Analyses for the following parameters were conducted at the SESD lab in Athens, Georgia: heavy metals scan, nutrients which includes total phosphorous (TP), NO2+NO3, NH3, and TKN, extractable organic compounds, pesticides, and PCBs. The sample was transferred to a glass pan and thoroughly mixed. The sample was alloquated into two 236.6 ml. glass containers and preserved by storing at 4 C until analyzed. One container was analyzed for extractable organic compounds and the other was analyzed for metals and nutrients. In addition, at stations B01, B04, B07 and B12, one additional container was filled from the sample and analyzed for dioxins. Due to tight budgetary constraints, only four discrete samples for dioxin analyses were allocated to this study.

Benthic Macroinvertebrate Infauna

Sediment from a separate deployment of the grab were collected to obtain benthic macroinvertebrate organisms. On-board processing involved washing the sample through a #35 screen (0.5mm). The sample retained on the screen after washing was preserved in 10% seawater formalin with staining solution. Benthic containers were labeled both internally and externally and stored for transfer to contract lab facilities. The details of sorting and identification of infaunal taxa are described in Vittor, 2007.

All sampling procedures and sample preservation for analyses were according to the SESD Standard Operating Procedures (SOP), (US EPA 1996, 2002).

RESULTS AND DISCUSSION

Water Quality

The results of the water quality profile are summarized in Table 2. The data showed the site's water column to be extremely well-mixed, evident by the narrow ranges seen within all the parameters measured.

Dissolved oxygen during the sample period exhibited a narrow range (6.14 – 6.28 mg/L; see Table 2 and Figure 2) while turbidity ranged from 1.51 to 2.85 NTUs (see Table 2 and Figure 2). Temperature and salinity (see Table 2 and Figure 3) profiles also showed that the waters sampled at the Brunswick ODMDS are well-mixed. Temperatures ranged from 22.30 to 22.91 ºC; salinities ranged from 33.02 to 33.73 ppt.

Chemical analyses of the water samples collected as part of this study showed that, with the exception of three metals and several dioxin congeners, all analytes to be undetectable within the specified target reporting limits. The metals that were detected were aluminum (60 - 86 ug/L), arsenic (12 – 15 ug/L), and copper (8.4 ug/L).

Seafloor Sampling

Sediment Particle Size.

The results of the sediment particle size analyses are given in Table 3. Both zones sampled during this survey are dominated by sediments in the sand fraction with small percentages of both gravel and silt/clays (see Table 3 and Figure 4).

Sediment Chemistry.

As with water chemical analyses, only select dioxin congerers and nine metals were detected in sediments taken from the ODMDS and surrounding area. The metals data is summarized in Table 4. For all nine metals detected, the mean concentration of the sediments were consistently lower for stations within the ODMDS than those outside the site. With the exception of results for iron, variability was also much higher at stations surrounding the site than at stations within the site.

Benthic Macroinvertebrate Infauna.

The benthic infauna data is detailed and summarized in “Brunswick, Georgia ODMDS 2006 Benthic Community Assessment “(Vittor, 2007). Polychaetes dominated the total assemblage (59.5%), and also ranked first in number of taxa (48.3%) represented. In terms of abundance, the polychaetes were followed by malacostracans (29.8%), bivalves (2.5%) and ophiuroids (1.6%): by taxa, the polychaetes were followed by malacostracans (23.3%), bivalves (12.2%) and gastropods (5.8%). In general, the stations representing both inside the ODMDS and outside the ODMDS were dominated by a mixed assemblage of polychaetes and arthropods.

The dominant taxa found inside the ODMDS were the polychaete *Spiophanes bombyx* (31.95 %), the amphipod *Oxyurostylis smithi* (11.6%) and the amphipod *Protohaustorius* sp. B (5.75%).

The dominant taxa found outside the ODMDS were the polychaete *Spiophanes bombyx* (19.81%), the polychaete *Mediomastus* [LPIL] (12.01%), the polychaete *Mediomastus ambiseta* (8.23%), the amphipod *Metatiron tropakis* (7.24%) and the amphipod *Oxyurostylis smithi* (7.04%).

Mean densities were 7937.8 organisms/m^2 within the ODMDS and 104475.0 organisms/m^2 outside the ODMDS. There was not a significant difference in density between stations inside vs. outside (Vittor, 2007).

The mean number of taxa was 42.3 taxa/station inside the ODMDS 46.5 taxa/station outside the ODMDS. Again, there was not a significant difference in mean number of taxa between stations inside vs. outside (Vittor, 2007).

The results of cluster, ANOSIM and SIMPLER analyses are discussed in detail within Vittor, 2007. In summary, these results indicate that assemblages inside and outside the ODMDS are similar. Table 5 lists the infaunal community parameters by station.

CONCLUSIONS

When comparing the various study parameters, no significant differences are found between the benthic infaunal communities of the Brunswick ODMDS and those of the surrounding area. Table 6 summarizes the main parameters of this study, demonstrating that no physical, chemical nor biological difference can be seen.

The mean grain size is nearly identical both within and outside the ODMDS. While both taxa richness and density of the infaunal communities show numerical higher means outside the site than within, there is no statistical difference between the two areas. Statistical analysis was not done to compare metals concentrations due to the fact that sediments within the site averaged lower than those outside the site. The main objective of Status and Trends studies is identifying 'signs/symptoms' of potential adverse impacts due to dumping of dredged materials within the ODMDS. The presence of significantly elevated contaminant levels within the site compared to outside would be such a 'sign/symptom.' In this case, the reverse was true.

In conclusion, the data collected in May 2006 shows that the benthic communities within the Brunswick ODMDS compare favorably with those adjacent to the dump site, and at the most basic levels of comparison, no long term adverse impact from dumping of dredged material has occurred.
