

EPA Region 10 HAP and VOC Emission Factors for Lumber Drying, November 2019

This spreadsheet calculates and compiles hazardous air pollutant (HAP) and volatile organic compound (VOC) emission factors (EF) in units of pounds of pollutant per thousand board feet of lumber dried (lb/mbf) that are preferred by EPA Region 10 for estimating emissions from indirect steam-heated batch lumber drying kilns. The EFs are based on actual lab-scale emission test data when available. When no suitable HAP or VOC test data is available for a species of wood (e.g western red cedar, engelmann spruce, larch and western white pine), EFs for similar species are substituted. When there are more than one similar species, the highest of the EF for the similar species is substituted. When test data is available for some individual HAP (methanol, formaldehyde, acetaldehyde, propionaldehyde and acrolein) or VOC compounds (ethanol and acetic acid) but not others, data substitution for that species of wood is not performed so as to maintain the integrity of the WPP1 VOC EF calculation. Only douglas fir and ponderosa pine EF are supported by full suite of test data for all seven aforementioned compounds.

A summary of the EFs for each species of wood is included on this sheet. The sheets that follow present the original test data as well as the calculations for creating each EF. There are two sheets per lumber species: one for HAPs and one for VOCs. The methanol, formaldehyde and VOC EF are temperature dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. Because acetaldehyde, propionaldehyde and acrolein emissions across different species are not consistently dependent upon maximum drying temperature, EF are calculated by averaging test results. Whereas HAP EF are derived in the HAP sheets, EF for individual VOC ethanol and acetic acid are derived in the VOC sheets for douglas fir and ponderosa pine (only wood species undergoing testing for these two VOC compounds).

Species	WPP1 VOC ^{1,2} (lb/mbf)	Methanol ² (lb/mbf)	Formaldehyde ² (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)

¹ VOC emissions approximated consistent with EPA's Interim VOC Measurement Protocol for the Wood Products Industry - July 2007 (WPP1 VOC). WPP1 VOC underestimates emissions when the mass-to-carbon ratio of unidentified VOC exceeds that of propane. Ethanol and acetic acid are examples of compounds that contribute to lumber drying VOC emissions (for some species more than others), and both have mass-to-carbon ratios exceeding that of propane. Contribution of ethanol and acetic acid to VOC emissions has been quantified here when emissions testing data is available.

² Because WPP1 VOC, methanol and formaldehyde emissions are dependent upon maximum drying temperature, a best-fit linear equation with dependent variable maximum temperature of heated air entering the lumber has been generated to model emissions, with a couple of exceptions. For engelmann spruce and lodgepole pine, a single VOC EF (based upon high-temperature drying) has been generated due to lack of sufficient test data to build a best-fit linear equation.

³ Western true firs consist of the following seven species classified in the same Abies genus: bristlecone fir, California red fir, grand fir, noble fir, pacific silver fir, subalpine fir and white fir.

Hazardous Air Pollutant Emission Factors for Drying Western True Fir Lumber

This sheet presents lab-scale HAP test data and calculations used to create HAP EF for drying western true fir lumber in an indirect steam-heated batch kiln. Western true fir consists of the following seven species classified in the same Abies genus: bristlecone fir, California red fir, grand fir, noble fir, pacific silver fir, subalpine fir and white fir. The methanol and formaldehyde EF are temperature dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The acetaldehyde EF reflects the results of a single test. No EF are presented for either propionaldehyde or acrolein as EPA Region 10 is not aware of any test data for those HAP.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Western True Fir HAP Emission Test Data by Drying Temperature¹

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)	Lumber Dimensions	Moisture Content ² (%) (Initial / Final)	Time to Final Moisture Content (hours)	HAP Sample Collection Technique	Reference
180	0.096	0.0022	no data	no data	no data	2x6	122.0 / 15	42.6	NCASI Method IM/CAN/WP-99.01 without cannisters.	3, 4, 5, 12, 14
180	0.148	0.0034	no data	no data	no data	2x6	133.2 / 15	46.9		
225	no data	no data	0.0550	no data	no data	2x4	170 / 13	54	Dinitrophenylhydrazine coated cartridges.	7
240	0.42	0.0156	no data	no data	no data	2x6	126.3 / 15	24	NCASI chilled impinger method.	5
240	0.419	0.0163	no data	no data	no data	2x6	119.0 / 15	24		

¹ Green highlight denotes data generated by testing conducted on the small-scale kiln at the University of Idaho. All other data was generated by testing conducted on the smaller of the two small-scale kilns at OSU.

² Dry basis. Moisture content = (weight of water / weight wood) x 100

Step Two: Adjust Western True Fir HAP Emission Test Data to Account for Bias in Underlying Small-Scale Kiln to Represent Full-Scale Kiln Emissions¹

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
180	0.0875	0.0016	no data	no data	no data
180	0.1348	0.0025	no data	no data	no data
225	no data	no data	0.0550	no data	no data
240	0.3827	0.0115	no data	no data	no data
240	0.3818	0.0120	no data	no data	no data

¹ Green highlighted results from the test conducted at the University of Idaho have not been adjusted because the kiln was not calibrated to a full-scale kiln.

Adjusted OSU emission test data value_i = (OSU reported emission test data value_i) X (NCASI TB No. 845 study full-scale kiln value_i/NCASI TB No. 845 study OSU small-scale kiln value_i)

where: OSU reported emission test data value_i is the emission rate "lb/mbf" for compound "i" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value_i is the average emission rate "lb/mbf" for compound "i" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value_i is the average emission rate "lb/mbf" for compound "i" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according the schedule employed by the full-scale kiln.

	NCASI TB No. 845 - Emission Rate (lb/mbf)				
	Methanol	Formaldehyde	Acetaldehyde	Propionaldehyde	Acrolein
Full-Scale Kiln	0.205	0.0155	0.039	0.001	0.006
OSU Kiln	0.225	0.0210	0.065	0.003	0.009

Step Three: Calculate Western True Fir HAP Emission Factors

Methanol ¹ (lb/mbf)	Formaldehyde ¹ (lb/mbf)	Acetaldehyde ² (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
0.00465x - 0.73360	0.00016x - 0.02764	0.0550	no data	no data

¹ Because methanol and formaldehyde emissions are dependent upon drying temperature, best-fit linear equations model emissions with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

² The acetaldehyde EF reflects the results of a single test.

Volatile Organic Compound Emission Factors for Drying Western True Fir Lumber

This sheet presents lab-scale EPA Reference Method 25A (RM25A) and speciated VOC test data and calculations used to create VOC EF for drying western true fir lumber in an indirect steam-heated batch kiln. Western true fir consists of the following seven species classified in the same Abies genus: bristlecone fir, California red fir, grand fir, noble fir, pacific silver fir, subalpine fir and white fir. RM25A has some limitations in that it misses some pollutant compounds (or portions thereof) that are VOC and known to exist and reports the results "as carbon" which only accounts for the carbon portion of each compound measured. The missed pollutant compounds (some HAP and some non-HAP) are accounted for through separate testing. RM25A test data is adjusted to fully account for three known pollutant compounds that are VOC using separate speciated test data and is reported "as propane" to better represent all of the unspciated VOC compounds. This technique is consistent with EPA's Interim VOC Measurement Protocol for the Wood Products Industry - July 2007 (WPP1 VOC) except that the RM25A results are adjusted to account for not only methanol and formaldehyde but also for acetaldehyde in this case.

More specifically, ten separate drying-temperature-specific VOC emission rates (upon which a best-fit linear equation will be established) are calculated based upon underlying RM25A and speciated VOC test data as indicated above. Temperature-specific methanol and formaldehyde emission rates are calculated for each temperature at which RM25A testing was performed using temperature-dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The temperature-independent acetaldehyde emission rate reflects the result of a single test. EPA Region 10 is not aware of any further speciated VOC test data. That portion of the (speciated) VOC compounds that are measured by the RM25A test method (based on known flame ionization detector response factors) is subtracted from the RM25A measured emission rate. The remaining "unspciated" RM25A emission rate is adjusted to represent propane rather than carbon and then added to the speciated VOC emission rate to provide the "total" temperature-specific VOC emission rate. The resultant VOC EF is a 10-point best-fit linear equation with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Note that reporting the unspciated VOC as propane (mass-to-carbon ratio of 1.22 and a response factor of 1) may underestimate the actual mass of VOC for certain wood species because VOC compounds like ethanol and acetic acid with higher mass-to-carbon ratios (1.92 and 2.5, respectively) and lower response factors (0.66 and 0.575, respectively) can be a significant portion of the total VOC. Based upon the mass-to-carbon ratios and response factors noted above, 1 lb/mbf ethanol is reported as 0.4194 lb/mbf propane and 1 lb/mbf acetic acid is reported as 0.2806 lb/mbf propane through the use of EPA Reference Method 25A unless compound-specific sampling and analysis is performed. The contribution of ethanol and acetic acid has been quantified through sampling and analysis for douglas fir and ponderosa pine. For douglas fir, ethanol's contribution over three tests was measured to be 0, 1.4 and 5.4 percent of WPP1 VOC, and acetic acid's contribution over the same three tests was measured to be 37, 20 and 13 percent of WPP1 VOC. For ponderosa pine, ethanol's contribution over one test was measured to be 32 percent of WPP1 VOC, and acetic acid's contribution over the same test was measured to be 6.4 percent. Without western true fir lumber drying test data for ethanol and acetic acid, EPA assumes propane adequately represents the mix of unspciated VOC.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Western True Fir RM25A VOC Emission Test Data by Drying Temperature¹

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)	Lumber Dimensions	Moisture Content ² (%) (Initial/Final)	Time to Final Moisture Content (hours)	Method 25A Analyzer	Reference

190	0.42
200	0.44
225	0.39
240	0.52
240	0.50

¹ Green highlighted results from the test conducted at the University of Idaho have not been adjusted because the kiln was not calibrated to a full-scale kiln.

Adjusted OSU emission test data value = (OSU reported emission test data value) X (NCASI TB No. 845 study full-scale kiln value/NCASI TB No. 845 study OSU small-scale kiln value)

where: OSU reported emission test data value is the RM25A VOC as carbon emission rate "lb/mbf" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according to the schedule employed by the full-scale kiln.

NCASI TB No. 845 - Emission Rate (lb/mbf)

RM25A VOC as carbon

Full-Scale Kiln 3.53333
OSU Kiln 4.25000

Step Three: Calculate/Compile Western True Fir Speciated HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing¹

Maximum Dry Bulb Temperature (°F)	Methanol ² (lb/mbf)	Formaldehyde ³ (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
180	0.1034	0.0012	0.0550	no data	no data
190	0.1499	0.0028			
200	0.1964	0.0044			
225	0.3127	0.0084			
240	0.3824	0.0108			

¹ See western true fir HAP sheet for lab-scale test data and calculations.

² Methanol EF = 0.00465x - 0.73360; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

³ Formaldehyde EF = 0.00016x - 0.02764; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Step Four: Compile True Fir Speciated Non-HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing

Maximum Dry Bulb Temperature (°F)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)
180	no data	no data
190		
200		
225		
240		

Step Five: Convert Western True Fir Speciated HAP and Non-HAP Emission Factors to "as Carbon" and Total

Speciated Compound "X" expressed as carbon = (RF_X) X (SC_X) X [(MW_C) / (MW_X)] X [(#C_X) / (#C_C)]

where: RF_X represents the flame ionization detector (FID) response factor (RF) for speciated compound "X"

SC_X represents emissions of speciated compound "X" expressed as the entire mass of compound emitted

MW_C equals "12.0110" representing the molecular weight (MW) for carbon as carbon is becoming the "basis" for expressing mass of speciated compound "X"

MW_X represents the molecular weight for speciated compound "X"

#C_X represents the number of carbon atoms in speciated compound "X"

#C_C equals "1" as the single carbon atom is becoming the "basis" for expressing mass of speciated compound "X"

Maximum Dry Bulb Temperature (°F)	Methanol as Carbon (lb/mbf)	Formaldehyde as Carbon (lb/mbf)	Acetaldehyde as Carbon (lb/mbf)	Propionaldehyde as Carbon (lb/mbf)	Acrolein as Carbon (lb/mbf)	Ethanol as Carbon (lb/mbf)	Acetic Acid as Carbon (lb/mbf)	Speciated Compounds as Carbon (lb/mbf)

240	0.52	0.1182	0.3972	0.4861
240	0.50	0.1182	0.3806	0.4658

Propane Mass Conversion Factor

X 1.2238 =

Method 25A VOC as propane without speciated compounds = (VOC_C) X (1/RF_{C3H8}) X [(MW_{C3H8}) / (MW_C)] X [(#C_C) / (#C_{C3H8})]

where: VOC_C represents Method 25A VOC as carbon without speciated compounds

RF_{C3H8} equals "1" and represents the FID RF for propane. All alkanes, including propane, have a RF of 1.

MW_{C3H8} equals "44.0962" and represents the molecular weight for propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

MW_C equals "12.0110" and represents the molecular weight for carbon

#C_C equals "1" as the single carbon atom was the "basis" for which Method 25A VOC test results were determined as illustrated in Step One of this spreadsheet

#C_{3H8} equals "3" as three carbon atoms are present within propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

Note: The following portion from the equation immediately above, $(1/R_{C_3H_8}) \times [(MW_{C_3H_8}) / (MW_O)] \times [(#C_C) / (#C_{C_3H_8})]$, equals 1.2238 and can be referred to as the "propane mass conversion factor."

Step Seven: Calculate WPP1 VOC by Adding Speciated HAP and Non-HAP Compounds to Western True Fir RM25A VOC Emission Factors "as Propane"

WPP1 VOC = Method 25A VOC as propane without speciated compounds + \sum speciated compounds expressed as the entire mass of compound

FROM STEP SIX		FROM STEP THREE					FROM STEP FOUR		WPP1 VOC
Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Propane without Speciated Compounds (lb/mbf)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)	(lb/mbf)

225	0.3557	0.3127	0.0084						0.7317
240	0.4861	0.3824	0.0108						0.9343
240	0.4658	0.3824	0.0108						0.9140

Step Eight: Generate Western True Fir Best-Fit Linear Equation with Dependent Variable Maximum Drying Temperature of Heated Air Entering the Lumber to Model WPP1 VOC Emissions

WPP1 VOC (lb/mbf): $0.00817x - 1.02133$; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber

Hazardous Air Pollutant Emission Factors for Drying Western Hemlock Lumber

This sheet presents lab-scale test data and calculations used to create HAP EF for drying western hemlock lumber in an indirect steam-heated batch kiln. The methanol and formaldehyde EF are temperature dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The acetaldehyde, propionaldehyde and acrolein EF are calculated by averaging test results.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Western Hemlock HAP Emission Test Data by Drying Temperature¹

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)	Lumber Dimensions	Moisture Content ² (%) (Initial / Final)	Time to Final Moisture Content (hours)	HAP Sample Collection Technique	Reference

235	0.1704	0.0033	0.0504	0.0005	0.0013

Adjusted OSU emission test data value_i = (OSU reported emission test data value_i) X (NCASI TB No. 845 study full-scale kiln value_i/NCASI TB No. 845 study OSU small-scale kiln value_i)

where: OSU reported emission test data value_i is the emission rate "lb/mbf" for compound "i" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value_i is the average emission rate "lb/mbf" for compound "i" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value_i is the average emission rate "lb/mbf" for compound "i" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according the schedule employed by the full-scale kiln.

	NCASI TB No. 845 - Emission Rate (lb/mbf)				
	Methanol	Formaldehyde	Acetaldehyde	Propionaldehyde	Acrolein
Full-Scale Kiln	0.205	0.0155	0.039	0.001	0.006
OSU Kiln	0.225	0.0210	0.065	0.003	0.009

Step Three: Calculate Western Hemlock HAP Emission Factors

Methanol ¹ (lb/mbf)	Formaldehyde ¹ (lb/mbf)	Acetaldehyde ² (lb/mbf)	Propionaldehyde ² (lb/mbf)	Acrolein ² (lb/mbf)
0.00249x - 0.39750	0.000046x - 0.007622	0.0677	0.0004	0.0012

¹ Because methanol and formaldehyde emissions are dependent upon maximum drying temperature, best-fit linear equations model emissions with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber

² Because acetaldehyde, propionaldehyde and acrolein emissions across different species are not consistently dependent upon maximum drying temperature, EF are calculated by averaging test results.

Volatile Organic Compound Emission Factors for Drying Western Hemlock Lumber

This sheet presents lab-scale EPA Reference Method 25A (RM25A) and speciated VOC test data and calculations used to create VOC EF for drying western hemlock lumber in an indirect steam-heated batch kiln. RM25A has some limitations in that it misses some pollutant compounds (or portions thereof) that are VOC and known to exist and reports the results "as carbon" which only accounts for the carbon portion of each compound measured. The missed pollutant compounds (some HAP and some non-HAP) are accounted for through separate testing. RM25A test data is adjusted to fully account for five known pollutant compounds that are VOC using separate speciated test data and is reported "as propane" to better represent all of the unspciated VOC compounds. This technique is consistent with EPA's Interim VOC Measurement Protocol for the Wood Products Industry - July 2007 (WPP1 VOC) except that the RM25A results are adjusted to account for not only methanol and formaldehyde but also for acetaldehyde, propionaldehyde and acrolein in this case.

More specifically, twenty-three separate drying-temperature-specific VOC emission rates (upon which a best-fit linear equation will be established) are calculated based upon underlying RM25A and speciated VOC test data as indicated above. Temperature-specific methanol and formaldehyde emission rates are calculated for each temperature at which RM25A testing was performed using temperature-dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The temperature-independent acetaldehyde, propionaldehyde and acrolein emission rates reflect the average of all test results independent of the temperature of heated air entering the lumber. EPA Region 10 is not aware of any further speciated VOC test data. That portion of the (speciated) VOC compounds that are measured by the RM25A test method (based on known flame ionization detector response factors) is subtracted from the RM25A measured emission rate. The remaining "unspciated" RM25A emission rate is adjusted to represent propane rather than carbon and then added to the speciated VOC emission rate to provide the "total" temperature-specific VOC emission rate. The resultant VOC EF is a 23-point best-fit linear equation with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Note that reporting the unspciated VOC as propane (mass-to-carbon ratio of 1.22 and a response factor of 1) may underestimate the actual mass of VOC for certain wood species because VOC compounds like ethanol and acetic acid with higher mass-to-carbon ratios (1.92 and 2.5, respectively) and lower response factors (0.66 and 0.575, respectively) can be a significant portion of the total VOC. Based upon the mass-to-carbon ratios and response factors noted above, 1 lb/mbf ethanol is reported as 0.4194 lb/mbf propane and 1 lb/mbf acetic acid is reported as 0.2806 lb/mbf propane through the use of EPA Reference Method 25A unless compound-specific sampling and analysis is performed. The contribution of ethanol and acetic acid has been quantified through sampling and analysis for douglas fir and ponderosa pine. For douglas fir, ethanol's contribution over three tests was measured to be 0, 1.4 and 5.4 percent of WPP1 VOC, and acetic acid's contribution over the same three tests was measured to be 37, 20 and 13 percent of WPP1 VOC. For ponderosa pine, ethanol's contribution over one test was measured to be 32 percent of WPP1 VOC, and acetic acid's contribution over the same test was measured to be 6.4 percent. Without western hemlock lumber drying test data for ethanol and acetic acid, EPA assumes propane adequately represents the mix of unspciated VOC.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Western Hemlock RM25A VOC Emission Test Data by Drying Temperature^{1,2}

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)	Lumber Dimensions	Moisture Content ³ (%) (Initial/Final)	Time to Final Moisture Content (hours)	Method 25A Analyzer	Reference

¹ Blue highlight denotes data not considered by EPA Region 10 in 2012. The four test runs not considered here were obtained from a single "sample" and appeared to use a much longer drying cycle than would be in common use in the Pacific Northwest. Therefore, these highlighted values were not used in the EF derivation.

² Green highlight denotes data generated by testing conducted on the small-scale kiln at the University of Idaho. All other data was generated by testing conducted on the smaller of the two small-scale kilns at OSU.

³ Dry basis. Moisture content = (weight of water / weight wood) x 100

Step Two: Adjust Western Hemlock VOC Emission Test Data to Account for Bias in Underlying Small-Scale Kiln to Represent Full-Scale Kiln Emissions¹

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)
180	0.141

235	0.205
235	0.188

¹ Green highlighted results from the test conducted at the University of Idaho have not been adjusted because the kiln was not calibrated to a full-scale kiln.

Adjusted OSU emission test data value = (OSU reported emission test data value) X (NCASI TB No. 845 study full-scale kiln value/NCASI TB No. 845 study OSU small-scale kiln value)

where: OSU reported emission test data value is the RM25A VOC as carbon emission rate "lb/mbf" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according to the schedule employed by the full-scale kiln.

NCASI TB No. 845 - Emission Rate (lb/mbf)
RM25A VOC as carbon

Full-Scale Kiln	3.53333
OSU Kiln	4.25000

Step Three: Calculate/Compile Western Hemlock Speciated HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing¹

Maximum Dry Bulb Temperature (°F)	Methanol ² (lb/mbf)	Formaldehyde ³ (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
180	0.0507	0.0007	0.0677	0.0004	0.0012
200	0.1005	0.0016			
215	0.1379	0.0023			
225	0.1628	0.0027			
235	0.1877	0.0032			

¹ See western hemlock HAP sheet for lab-scale test data and calculations.

² Methanol EF = 0.00249x - 0.39750; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

³ Formaldehyde EF = 0.000046x - 0.007622; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Step Four: Compile Western Hemlock Speciated Non-HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing

Maximum Dry Bulb Temperature (°F)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)
180	no data	no data
200		
215		
225		
235		

Step Five: Convert Western Hemlock Speciated HAP and Non-HAP Emission Factors to "as Carbon" and Total

Speciated Compound "X" expressed as carbon = (RF_x) X (SC_x) X [(MW_C) / (MW_x)] X [(#C_x) / (#C_C)]

where: RF_x represents the flame ionization detector (FID) response factor (RF) for speciated compound "X"

SC_x represents emissions of speciated compound "X" expressed as the entire mass of compound emitted

MW_C equals "12.0110" representing the molecular weight (MW) for carbon as carbon is becoming the "basis" for expressing mass of speciated compound "X"

MW_x represents the molecular weight for speciated compound "X"

#C_x represents the number of carbon atoms in speciated compound "X"

#C_C equals "1" as the single carbon atom is becoming the "basis" for expressing mass of speciated compound "X"

Maximum Dry Bulb Temperature (°F)	Methanol as Carbon (lb/mbf)	Formaldehyde as Carbon (lb/mbf)	Acetaldehyde as Carbon (lb/mbf)	Propionaldehyde as Carbon (lb/mbf)	Acrolein as Carbon (lb/mbf)	Ethanol as Carbon (lb/mbf)	Acetic Acid as Carbon (lb/mbf)

MINUS
⇒

EQUALS
⇒

Propane Mass Conversion Factor
X 1.2238 =

Method 25A VOC as propane without speciated compounds = $(VOC_C) \times (1/RF_{C_3H_8}) \times [(MW_{C_3H_8}) / (MW_C)] \times [(#C_C) / (#C_{C_3H_8})]$

where: VOC_C represents Method 25A VOC as carbon without speciated compounds

$RF_{C_3H_8}$ equals "1" and represents the FID RF for propane. All alkanes, including propane, have a RF of 1.

$MW_{C_3H_8}$ equals "44.0962" and represents the molecular weight for propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

MW_C equals "12.0110" and represents the molecular weight for carbon

$#C_C$ equals "1" as the single carbon atom was the "basis" for which Method 25A VOC test results were determined as illustrated in Step One of this spreadsheet

$#C_{C_3H_8}$ equals "3" as three carbon atoms are present within propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

Note: The following portion from the equation immediately above, $(1/RF_{C_3H_8}) \times [(MW_{C_3H_8}) / (MW_C)] \times [(#C_C) / (#C_{C_3H_8})]$, equals 1.2238 and can be referred to as the "propane mass conversion factor."

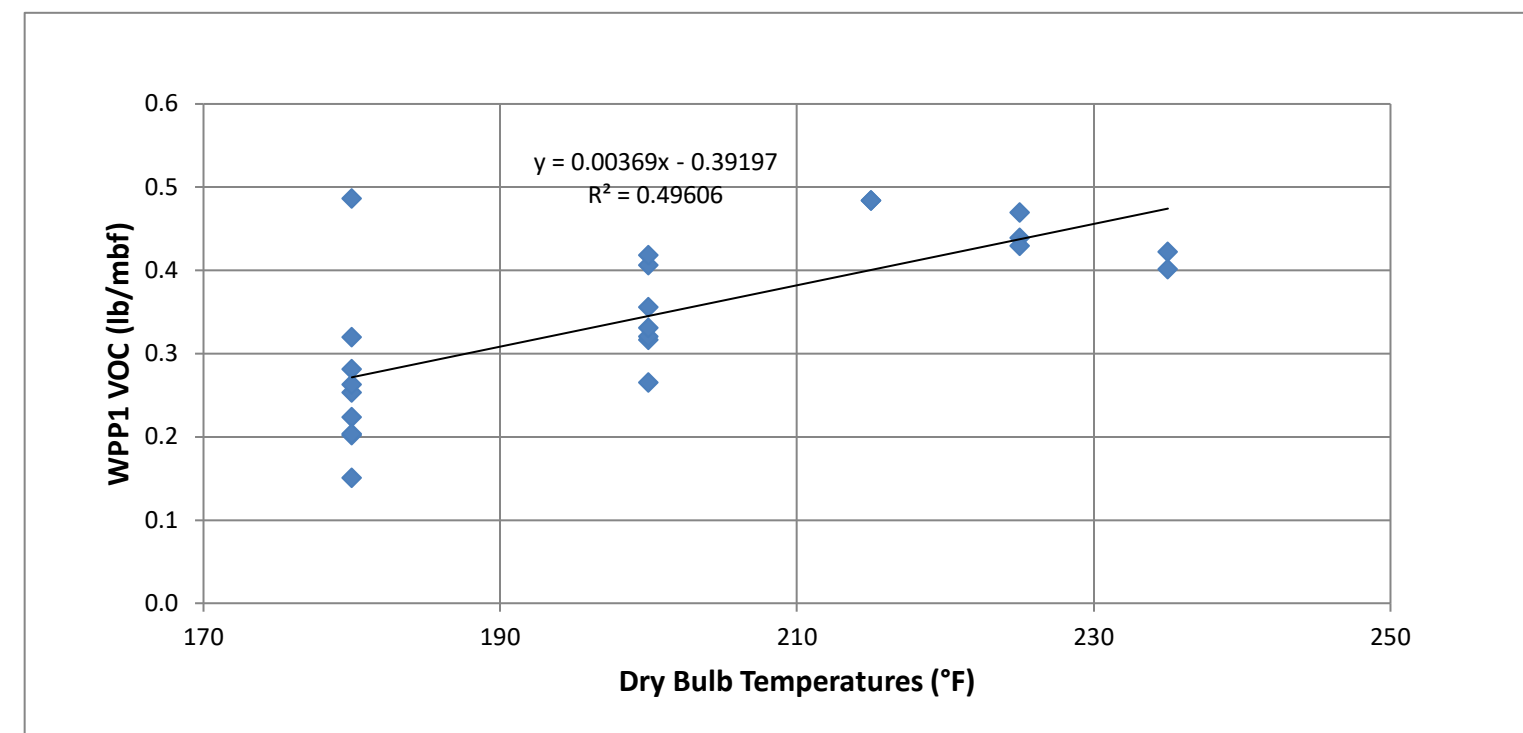

Step Seven: Calculate WPP1 VOC by Adding Speciated HAP and Non-HAP Compounds to Western Hemlock RM25A VOC Emission Factors "as Propane"

WPP1 VOC = Method 25A VOC as propane without speciated compounds + \sum speciated compounds expressed as the entire mass of compound

Maximum Dry Bulb Temperature (°F)	FROM STEP SIX	FROM STEP THREE					FROM STEP FOUR		WPP1 VOC (lb/mbf)

Step Seven: Generate Western Hemlock Best-Fit Linear Equation with Dependent Variable Maximum Drying Temperature of Heated Air Entering the Lumber to Model WPP1 VOC Emissions

WPP1 VOC (lb/mbf): $0.00369x - 0.39197$; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber

Hazardous Air Pollutant Emission Factors for Drying Western Red Cedar Lumber

This sheet presents the HAP EF for drying western red cedar lumber. EPA Region 10 is not aware of any HAP emission testing of western red cedar. When no test data is available for any HAP, data for a similar species is substituted as noted. When there are more than one similar species, the highest of the EF for the similar species is substituted.

In the absence of western red cedar test data, western true fir test data has been substituted for methanol and formaldehyde and western hemlock test data has been substituted for acetaldehyde, propionaldehyde and acrolein. Western red cedar is similar to western true firs and western hemlock in that all species are non-resinous softwood species in the scientific classification order Pinales. For methanol and formaldehyde, western true fir EF are greater. For acetaldehyde, western hemlock EF is greater. EPA Region 10 is not aware of any western true fir test data for either propionaldehyde or acrolein. See the western true fir and western hemlock HAP sheets for lab-scale test data and calculations.

Western Red Cedar (Western True Firs and Western Hemlock Substitution) HAP Emission Factors

Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
0.00465x - 0.73360	0.00016x - 0.02764	0.0677	0.0004	0.0012

Volatile Organic Compound Emission Factors for Drying Western Red Cedar Lumber

This sheet presents the VOC EF for drying western red cedar lumber. EPA Region 10 is aware of two tests being conducted while drying western red cedar lumber, and both were conducted at 160°F. Because VOC emissions increase with maximum drying temperature, employing an EF based upon testing at 160°F would underreport emissions when drying at maximum drying temperatures greater than 160°F. A temperature of 160°F is not a particularly high drying temperature. When little or no test data is available, data for a similar species is substituted as noted. When there are more than one similar species, the highest of the EF for the similar species is substituted.

Given the limited western red cedar test data, western true fir test data has been substituted. Western red cedar is similar to western true firs and western hemlock in that all species are non-resinous softwood species in the scientific classification order Pinales. Western true fir VOC emissions are greater than western hemlock VOC emissions. See the western true fir and western hemlock VOC sheets for lab-scale test data and calculations.

Western Red Cedar (Western True Firs Substitution) WPP1 VOC Emission Factor

WPP1 VOC (lb/mbf): $0.00817x - 1.02133$; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumt

Hazardous Air Pollutant Emission Factors for Drying Douglas Fir Lumber

This sheet presents lab-scale test data and calculations used to create HAP EF for drying douglas fir lumber in an indirect steam-heated batch kiln. The methanol and formaldehyde EF are temperature dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The acetaldehyde, propionaldehyde and acrolein EF are calculated by averaging test results.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Douglas Fir HAP Emission Test Data by Drying Temperature¹

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)	Lumber Dimensions	Moisture Content ² (%) (Initial / Final)	Time to Final Moisture Content (hours)	HAP Sample Collection Technique	Reference

235	0.107	0.0032	0.040	0.0003	0.0008

¹ Green highlighted results from the test conducted at the University of Idaho have not been adjusted because the kiln was not calibrated to a full-scale kiln.

Adjusted OSU emission test data value_i = (OSU reported emission test data value_i) X (NCASI TB No. 845 study full-scale kiln value/NCASI TB No. 845 study OSU small-scale kiln value)

where: OSU reported emission test data value_i is the emission rate "lb/mbf" for compound "i" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value_i is the average emission rate "lb/mbf" for compound "i" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value_i is the average emission rate "lb/mbf" for compound "i" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according the schedule employed by the full-scale kiln.

	NCASI TB No. 845 - Emission Rate (lb/mbf)				
	Methanol	Formaldehyde	Acetaldehyde	Propionaldehyde	Acrolein
Full-Scale Kiln	0.205	0.0155	0.039	0.001	0.006
OSU Kiln	0.225	0.0210	0.065	0.003	0.009

Step Three: Calculate Douglas Fir HAP Emission Factors

Methanol ¹ (lb/mbf)	Formaldehyde ¹ (lb/mbf)	Acetaldehyde ² (lb/mbf)	Propionaldehyde ² (lb/mbf)	Acrolein ² (lb/mbf)
0.00114x - 0.16090	0.000028x - 0.003800	0.0275	0.0003	0.0005

¹ Because methanol and formaldehyde emissions are dependent upon drying temperature, best-fit linear equations model emissions with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

² Because acetaldehyde, propionaldehyde and acrolein emissions across different species are not consistently dependent upon maximum drying temperature, EF are calculated by averaging test results.

Volatile Organic Compound Emission Factors for Drying Douglas Fir Lumber

This sheet presents lab-scale EPA Reference Method 25A (RM25A) and speciated VOC test data and calculations used to create VOC EF for drying douglas fir lumber in an indirect steam-heated batch kiln. RM25A has some limitations in that it misses some pollutant compounds (or portions thereof) that are VOC and known to exist and reports the results "as carbon" which only accounts for the carbon portion of each compound measured. The missed pollutant compounds (some HAP and some non-HAP) are accounted for through separate testing. RM25A test data is adjusted to fully account for seven known pollutant compounds that are VOC using separate speciated test data and is reported "as propane" to better represent all of the unspciated VOC compounds. This technique is consistent with EPA's Interim VOC Measurement Protocol for the Wood Products Industry - July 2007 (WPP1 VOC) except that the RM25A results are adjusted to account for not only methanol and formaldehyde but also for acetaldehyde, propionaldehyde, acrolein, ethanol and acetic acid in this case.

More specifically, twenty-one separate drying-temperature-specific VOC emission rates (upon which a best-fit linear equation will be established) are calculated based upon underlying RM25A and speciated VOC test data as indicated above. Temperature-specific methanol, formaldehyde and ethanol emission rates are calculated for each temperature at which RM25A testing was performed using temperature-dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The temperature-independent acetaldehyde, propionaldehyde, acrolein and acetic acid emission rates reflect the average of all test results independent of the temperature of heated air entering the lumber. EPA Region 10 is not aware of any further speciated VOC test data. That portion of the (speciated) VOC compounds that are measured by the RM25A test method (based on known flame ionization detector response factors) is subtracted from the RM25A measured emission rate. The remaining "unspciated" RM25A emission rate is adjusted to represent propane rather than carbon and then added to the speciated VOC emission rate to provide the "total" temperature-specific VOC emission rate. The resultant VOC EF is a 21-point best-fit linear equation with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Douglas Fir RM25A VOC Emission Test Data by Drying Temperature¹

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)	Lumber Dimensions	Moisture Content ² (%) (Initial/Final)	Time to Final Moisture Content (hours)	Method 25A Analyzer	Reference

¹ Green highlighted results from the test conducted at the University of Idaho have not been adjusted because the kiln was not calibrated to a full-scale kiln.

Adjusted OSU emission test data value = (OSU reported emission test data value) X (NCASI TB No. 845 study full-scale kiln value/NCASI TB No. 845 study OSU small-scale kiln value)

where: OSU reported emission test data value is the RM25A VOC as carbon emission rate "lb/mbf" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according to the schedule employed by the full-scale kiln.

NCASI TB No. 845 - Emission Rate (lb/mbf)
RM25A VOC as carbon

Full-Scale Kiln 3.53333
OSU Kiln 4.25000

Step Three: Calculate/Compile Douglas Fir Speciated HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing¹

Maximum Dry Bulb Temperature (°F)	Methanol ² (lb/mbf)	Formaldehyde ³ (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
145	0.0044	0.0003	0.0275	0.0003	0.0005
160	0.0215	0.0007			
170	0.0329	0.0010			
175	0.0386	0.0011			
180	0.0443	0.0012			
200	0.0671	0.0018			
220	0.0899	0.0024			
235	0.1070	0.0028			

¹ See douglas fir HAP sheet for lab-scale test data and calculations.

² Methanol EF = 0.00114x - 0.16090; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

³ Formaldehyde EF = 0.000028x - 0.003800; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Step Four: Compile Douglas Fir Speciated Non-HAP Emission Test Data by Drying Temperature

Maximum Dry Bulb Temperature (°F)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)	Lumber Dimensions	Moisture Content ¹ (%) (Initial / Final)	Time to Final Moisture Content (hours)	VOC Sample Collection Technique	Reference
145	0.0000	0.166	2x4	49.6 / 15	39.7	NCASI ISS/FP-A105.01	Link to June 8, 2012 Exterior Wood Test Report
175	0.0010	0.094	2x4	32.5 / 15	17.8	NCASI ISS/FP-A105.01	Link to May 23, 2013 Sierra Pacific Industries - Centralia Test Report
175	0.0230	0.242	4x6	39.5 / 15	150	NCASI ISS/FP-A105.01	Link to March 24, 2015 Columbia Vista Test Report
200	0.0610	0.142	2x4	69.3 / 15	20.8	NCASI ISS/FP-A105.01	Link to February 10, 2012 Hampton Lumber - Morton Test Report

¹ Dry basis. Moisture content = (weight of water / weight wood) x 100

Step Five: Calculate Douglas Fir Speciated Non-HAP Emission Factors

Ethanol ¹ (lb/mbf)	Acetic Acid ² (lb/mbf)
0.00107x - 0.16537	0.1610

¹ Because ethanol emissions are dependent upon drying temperature, a best-fit linear equation models emissions with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

² Because acetic acid emissions are independent of drying temperature, EF is calculated by averaging test results.

Step Six: Calculate/Compile Douglas Fir Speciated Non-HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing

Maximum Dry Bulb Temperature (°F)	Ethanol ¹ (lb/mbf)	Acetic Acid (lb/mbf)
145	0	0.1610
160	0.00583	
170	0.01653	
175	0.02188	
180	0.02723	
200	0.04863	
220	0.07003	
235	0.08608	

¹ Ethanol EF = 0.00107x - 0.16537; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Step Seven: Convert Douglas Fir Speciated HAP and Non-HAP Emission Factors to "as Carbon" and Total

Speciated Compound "X" expressed as carbon = (RF_x) X (SC_x) X [(MW_C) / (MW_x)] X [(#C_x) / (#C_C)]

where: RF_x represents the flame ionization detector (FID) response factor (RF) for speciated compound "X"

SC_x represents emissions of speciated compound "X" expressed as the entire mass of compound emitted

MW_C equals "12.0110" representing the molecular weight (MW) for carbon as carbon is becoming the "basis" for expressing mass of speciated compound "X"

MW_x represents the molecular weight for speciated compound "X"

#C_x represents the number of carbon atoms in speciated compound "X"

#C_C equals "1" as the single carbon atom is becoming the "basis" for expressing mass of speciated compound "X"

Maximum Dry Bulb Temperature (°F)	Methanol as Carbon (lb/mbf)	Formaldehyde as Carbon (lb/mbf)	Acetaldehyde as Carbon (lb/mbf)	Propionaldehyde as Carbon (lb/mbf)	Acrolein as Carbon (lb/mbf)	Ethanol as Carbon (lb/mbf)	Acetic Acid as Carbon (lb/mbf)	Speciated Compounds as Carbon (lb/mbf)
145	0.0012	0	0.0075	0.0001	0.0002	0	0.0370	0.0461

MINUS → EQUALS → X 1.2238 =

Propane Mass Conversion Factor

$$\text{Method 25A VOC as propane without speciated compounds} = (\text{VOC}_C) \times (1/\text{RF}_{\text{C}_3\text{H}_8}) \times [(\text{MW}_{\text{C}_3\text{H}_8}) / (\text{MW}_C)] \times [(\#C_C) / (\#C_{\text{C}_3\text{H}_8})]$$

where: VOC_C represents Method 25A VOC as carbon without speciated compounds

RF_{C₃H₈} equals "1" and represents the FID RF for propane. All alkanes, including propane, have a RF of 1.

MW_{C₃H₈} equals "44.0962" and represents the molecular weight for propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

MW_C equals "12.0110" and represents the molecular weight for carbon

#C_C equals "1" as the single carbon atom was the "basis" for which Method 25A VOC test results were determined as illustrated in Step One of this spreadsheet

#C_{C₃H₈} equals "3" as three carbon atoms are present within propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

Note: The following portion from the equation immediately above, (1/RF_{C₃H₈}) X [(MW_{C₃H₈}) / (MW_C)] X [(#C_C) / (#C_{C₃H₈})], equals 1.2238 and can be referred to as the "propane mass conversion factor."

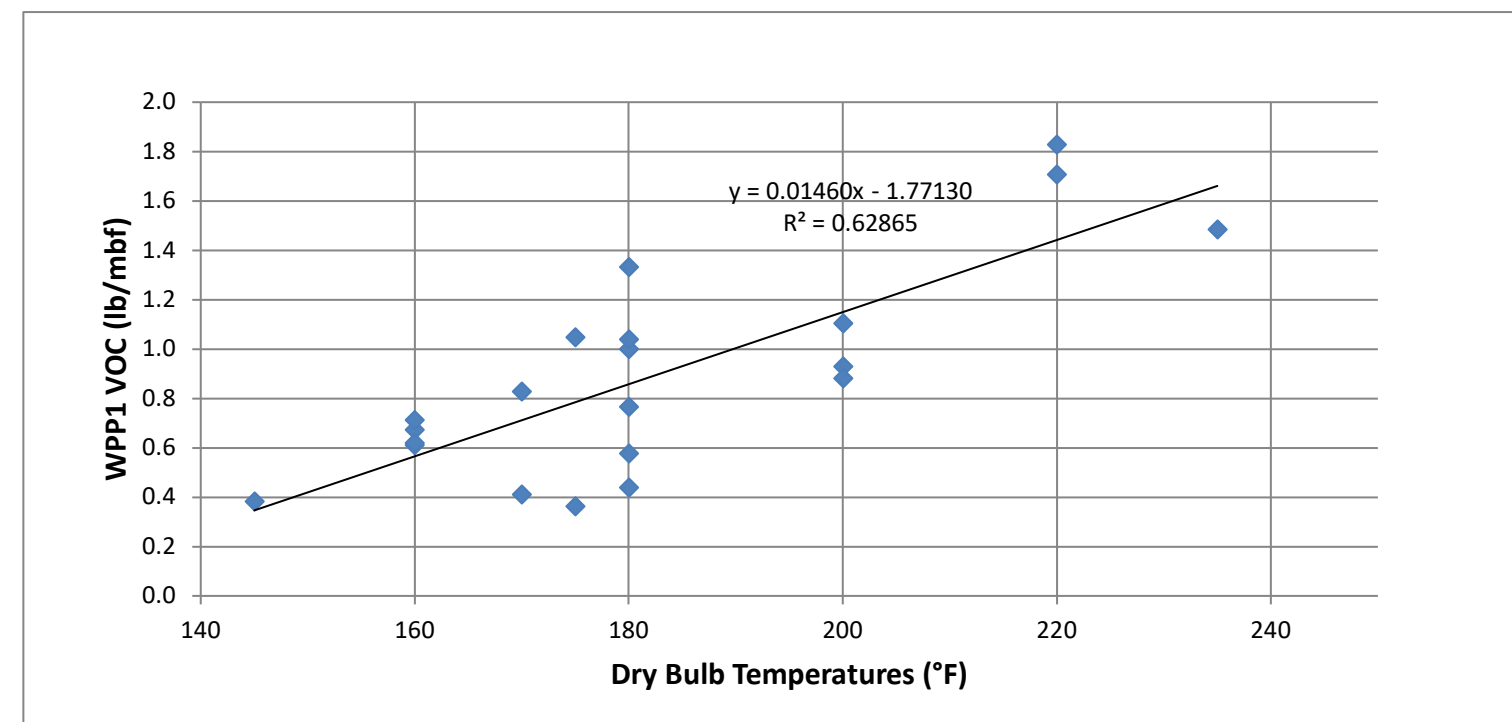

Step Nine: Calculate WPP1 VOC by Adding Speciated HAP and Non-HAP Compounds to Douglas Fir VOC Emission Factors "as Propane"

WPP1 VOC = Method 25A VOC as propane without speciated compounds + \sum speciated compounds expressed as the entire mass of compound

Maximum Dry Bulb Temperature (°F)	FROM STEP EIGHT	FROM STEP THREE					FROM STEP SIX		WPP1 VOC (lb/mbf)

Step Ten: Generate Douglas Fir Best-Fit Linear Equation with Dependent Variable Maximum Drying Temperature to Model WPP1 VOC Emissions

WPP1 VOC (lb/mbf): $0.01460x - 1.77130$; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber

Hazardous Air Pollutant Emission Factors for Drying Engelmann Spruce Lumber

This sheet presents lab-scale test data and calculations used to create HAP EF for engelmann spruce lumber in an indirect steam-heated batch kiln. EPA Region 10 is not aware of any HAP emission testing of engelmann spruce. When actual test data is not available, data for a similar species is substituted as noted. When there are more than one similar species, the highest of the EF for the similar species is substituted. In the absence of engelmann spruce test data, white spruce test data has been substituted. The two wood species are similar in that both are resinous softwood species in the scientific classification genus Picea.

The methanol and formaldehyde EF are temperature dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The acetaldehyde, propionaldehyde and acrolein EF are calculated by averaging test results.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Engelmann Spruce (White Spruce Substitution) HAP Emission Test Data by Drying Temperature

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)	Lumber Dimensions	Moisture Content ¹ (%) (Initial / Final)	Time to Final Moisture Content (hours)	HAP Sample Collection Technique	Reference
180	0.025	0.0013	0.036	0.0003	0.0005	2x4 or 2x6	33.5 / 15	no data	NCASI Method 105	18
235	0.078	0.0044	0.031	0.0007	0.001	2x4 or 2x6	32.7 / 15	no data		

¹ Dry basis. Moisture content = (weight of water / weight wood) x 100

Step Two: Adjust Engelmann Spruce (White Spruce Substitution) HAP Emission Test Data to Account for Bias in Underlying Small-Scale Kiln to Represent Full-Scale Kiln Emissions

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
180	0.023	0.0010	0.022	0.0001	0.0003
235	0.071	0.0032	0.019	0.0002	0.0007

Adjusted OSU emission test data value_i = (OSU reported emission test data value_i) X (NCASI TB No. 845 study full-scale kiln value_i/NCASI TB No. 845 study OSU small-scale kiln value_i)

where: OSU reported emission test data value_i is the emission rate "lb/mbf" for compound "i" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value_i is the average emission rate "lb/mbf" for compound "i" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value_i is the average emission rate "lb/mbf" for compound "i" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according the schedule employed by the full-scale kiln.

	NCASI TB No. 845 - Emission Rate (lb/mbf)				
	Methanol	Formaldehyde	Acetaldehyde	Propionaldehyde	Acrolein
Full-Scale Kiln	0.205	0.0155	0.039	0.001	0.006
OSU Kiln	0.225	0.0210	0.065	0.003	0.009

Step Three: Calculate Engelmann Spruce (White Spruce Substitution) HAP Emission Factors

Methanol ¹ (lb/mbf)	Formaldehyde ¹ (lb/mbf)	Acetaldehyde ² (lb/mbf)	Propionaldehyde ² (lb/mbf)	Acrolein ² (lb/mbf)
0.00088x - 0.13526	0.000042x - 0.006529	0.0201	0.0002	0.0005

¹ Because methanol and formaldehyde emissions are dependent upon drying temperature, best-fit linear equations model emissions with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

² Because acetaldehyde, propionaldehyde and acrolein emissions across different species are not consistently dependent upon maximum drying temperature, EF are calculated by averaging test results.

Volatile Organic Compound Emission Factors for Drying Engelmann Spruce Lumber

This sheet presents lab-scale EPA Reference Method 25A (RM25A) and speciated VOC test data and calculations used to create VOC EF for drying white spruce lumber in an indirect steam-heated batch kiln. EPA Region 10 is not aware of any HAP or VOC emission testing of englemann spruce. When actual test data is not available, data for a similar species is substituted as noted. When there are more than one similar species, the highest of the EF for the similar species is substituted. In the absence of englemann spruce test data, white spruce test data has been substituted. The two wood species are similar in that both are resinous softwood species in the scientific classification genus Picea. Although only one RM25A VOC test was performed while drying white spruce, it was performed while drying lumber at a relatively high maximum temperature of 235°F. Because emissions increase with maximum drying temperature, employing an EF based upon testing at 235°F would overreport emissions when drying at maximum drying temperatures less than than 235°F.

RM25A has some limitations in that it misses some pollutant compounds (or portions thereof) that are VOC and known to exist and reports the results "as carbon" which only accounts for the carbon portion of each compound measured. The missed pollutant compounds (some HAP and some non-HAP) are accounted for through separate testing. RM25A test data is adjusted to fully account for five known pollutant compounds that are VOC using separate speciated test data and is reported "as propane" to better represent all of the unspciated VOC compounds. This technique is consistent with EPA's Interim VOC Measurement Protocol for the Wood Products Industry - July 2007 (WPP1 VOC) except that the RM25A results are adjusted to account for not only methanol and formaldehyde but also for acetaldehyde, propionaldehyde and acrolein in this case.

More specifically, one VOC emission rate is calculated based upon underlying RM25A and speciated VOC test data as indicated above. Temperature-specific methanol and formaldehyde emission rates are calculated for each temperature at which RM25A testing was performed using temperature-dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The temperature-independent acetaldehyde, propionaldehyde and acrolein emission rates reflect the average of all test results independent of the temperature of heated air entering the lumber. EPA Region 10 is not aware of any further speciated VOC test data. That portion of the (speciated) VOC compounds that are measured by the RM25A test method (based on known flame ionization detector response factors) is subtracted from the RM25A measured emission rate. The remaining "unspciated" RM25A emission rate is adjusted to represent propane rather than carbon and then added to the speciated VOC emission rate to provide the "total" temperature-specific VOC emission rate.

Note that reporting the unspciated VOC as propane (mass-to-carbon ratio of 1.22 and a response factor of 1) may underestimate the actual mass of VOC for certain wood species because VOC compounds like ethanol and acetic acid with higher mass-to-carbon ratios (1.92 and 2.5, respectively) and lower response factors (0.66 and 0.575, respectively) can be a significant portion of the total VOC. Based upon the mass-to-carbon ratios and response factors noted above, 1 lb/mbf ethanol is reported as 0.4194 lb/mbf propane and 1 lb/mbf acetic acid is reported as 0.2806 lb/mbf propane through the use of EPA Reference Method 25A unless compound-specific sampling and analysis is performed. The contribution of ethanol and acetic acid has been quantified through sampling and analysis for douglas fir and ponderosa pine. For douglas fir, ethanol's contribution over three tests was measured to be 0, 1.4 and 5.4 percent of WPP1 VOC, and acetic acid's contribution over the same three tests was measured to be 37, 20 and 13 percent of WPP1 VOC. For ponderosa pine, ethanol's contribution over one test was measured to be 32 percent of WPP1 VOC, and acetic acid's contribution over the same test was measured to be 6.4 percent. Without white spruce lumber drying test data for ethanol and acetic acid, EPA assumes propane adequately represents the mix of unspciated VOC.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Engelmann Spruce (White Spruce Substitution) RM25A VOC Emission Test Data by Drying Temperature

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)	Lumber Dimensions	Moisture Content ¹ (%) (Initial/Final)	Time to Final Moisture Content (hours)	Method 25A Analyzer	Reference
235	0.11	2x4 or 2x6	32.7 / 15	no data	JUM VE-7	18

¹ Dry basis. Moisture content = (weight of water / weight wood) x 100

Step Two: Adjust Engelmann Spruce (White Spruce Substitution) VOC Emission Test Data to Account for Bias in Underlying Small-Scale Kiln to Represent Full-Scale Kiln Emissions

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)
235	0.09

Adjusted OSU emission test data value = (OSU reported emission test data value) X (NCASI TB No. 845 study full-scale kiln value/NCASI TB No. 845 study OSU small-scale kiln value)

where: OSU reported emission test data value is the RM25A VOC as carbon emission rate "lb/mbf" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according to the schedule employed by the full-scale kiln.

NCASI TB No. 845 - Emission Rate (lb/mbf)
RM25A VOC as carbon

Full-Scale Kiln	3.53333
OSU Kiln	4.25000

Step Three: Calculate/Compile Engelmann Spruce (White Spruce Substitution) Speciated HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing¹

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
235	0.0715	0.0033	0.0201	0.0002	0.0005

¹ See englemann spruce HAP sheet for lab-scale test data and calculations.

² Methanol EF = 0.00088x - 0.13526; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

³ Formaldehyde EF = 0.000042x - 0.006529; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Step Four: Compile Engelmann Spruce (White Spruce Substitution) Speciated Non-HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing

Maximum Dry Bulb Temperature (°F)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)
235	no data	no data

Step Five: Convert Engelmann Spruce (White Spruce Substitution) Speciated HAP Emission Factors to "as Carbon" and Total

Speciated Compound "X" expressed as carbon = (RF_x) X (SC_x) X [(MW_C) / (MW_x)] X [(#C_x) / (#C_C)]

where: RF_x represents the flame ionization detector (FID) response factor (RF) for speciated compound "X"

SC_x represents emissions of speciated compound "X" expressed as the entire mass of compound emitted

MW_C equals "12.0110" representing the molecular weight (MW) for carbon as carbon is becoming the "basis" for expressing mass of speciated compound "X"

MW_x represents the molecular weight for speciated compound "X"

#C_x represents the number of carbon atoms in speciated compound "X"

#C_C equals "1" as the single carbon atom is becoming the "basis" for expressing mass of speciated compound "X"

Maximum Dry Bulb Temperature (°F)	Methanol as Carbon (lb/mbf)	Formaldehyde as Carbon (lb/mbf)	Acetaldehyde as Carbon (lb/mbf)	Propionaldehyde as Carbon (lb/mbf)	Acrolein as Carbon (lb/mbf)	Ethanol as Carbon (lb/mbf)	Acetic Acid as Carbon (lb/mbf)	Speciated Compounds as Carbon (lb/mbf)
235	0.0193	0	0.0055	0.0001	0.0002	no data	no data	0.0251

SUM
⇒

Element and Compound Information

Element / Compound	FID RF ¹	Molecular Weight (lb/lb-mol)	Formula	Number of Carbon Atoms	Number of Hydrogen Atoms	Number of Oxygen Atoms	Reference
Methanol	0.72	32.042	CH ₄ O	1	4	1	1
Formaldehyde	0	30.0262	CH ₂ O	1	2	1	16
Acetaldehyde	0.5	44.053	C ₂ H ₄ O	2	4	1	20

Acrolein	0.66	56.064	C ₃ H ₄ O	3	4	1	20
Ethanol	0.66	46.0688	C ₂ H ₆ O	2	6	1	1
Acetic Acid	0.575	60.0524	C ₂ H ₄ O ₂	2	4	2	1
Propane	1	44.0962	C ₃ H ₈	3	8	0	16
Carbon	-	12.0110	C	1	-	-	-
Hydrogen	-	1.0079	H	-	1	-	-
Oxygen	-	15.9994	O	-	-	1	-

¹ FID RF = volumetric concentration or "instrument display" / compound's actual known concentration. Numerator and denominator expressed on same basis (ie. carbon, propane, etc) and concentration in units of "ppm."

Step Six: Subtract Speciated HAP and Non-HAP Compounds from Engelmann Spruce (White Spruce Substitution) VOC Emission Factors and Convert Result to "as Propane"

Method 25A VOC as propane without speciated compounds = (VOC_C) X (1/RF_{C3H8}) X [(MW_{C3H8}) / (MW_C)] X [(#C_C) / (#C_{C3H8})]

where: VOC_C represents Method 25A VOC as carbon without speciated compounds

RF_{C3H8} equals "1" and represents the FID RF for propane. All alkanes, including propane, have a RF of 1.

MW_{C3H8} equals "44.0962" and represents the molecular weight for propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

MW_C equals "12.0110" and represents the molecular weight for carbon

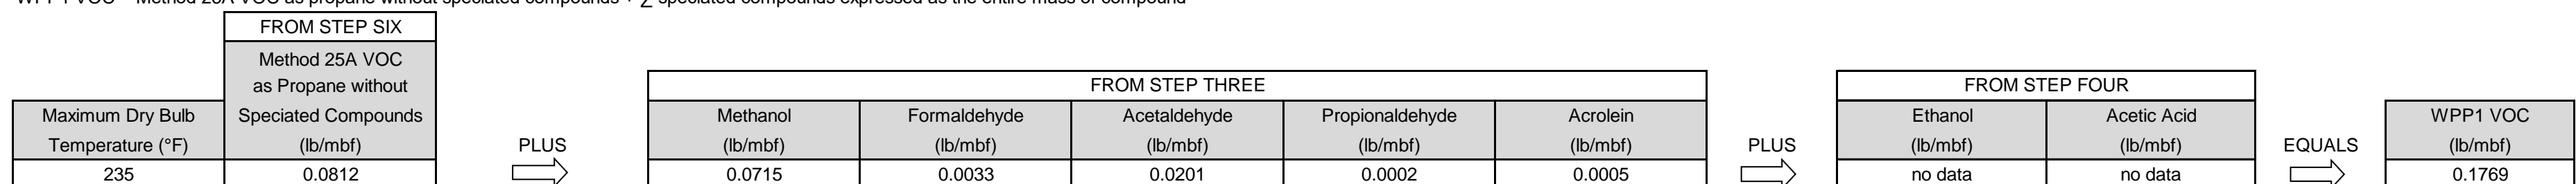

#C_C equals "1" as the single carbon atom was the "basis" for which Method 25A VOC test results were determined as illustrated in Step One of this spreadsheet

#C_{C3H8} equals "3" as three carbon atoms are present within propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

Note: The following portion from the equation immediately above, (1/RF_{C3H8}) X [(MW_{C3H8}) / (MW_C)] X [(#C_C) / (#C_{C3H8})], equals 1.2238 and can be referred to as the "propane mass conversion factor."

Step Seven: Calculate WPP1 VOC by Adding Speciated HAP and Non-HAP Compounds to Engelmann Spruce (White Spruce Substitution) VOC Emission Factors "as Propane"

WPP1 VOC = Method 25A VOC as propane without speciated compounds + Σ speciated compounds expressed as the entire mass of compound

Hazardous Air Pollutant Emission Factors for Drying Larch Lumber

This sheet presents the HAP EF for drying larch lumber. EPA Region 10 is not aware of any HAP emission testing of larch. Consistent with other species, when actual test data is not available, data for a similar species is substituted as noted. When there are more than one similar species, the highest of the EF for the similar species is substituted.

In the absence of larch test data, douglas fir test data has been substituted. Larch is similar to douglas fir, engelmann spruce, white spruce, lodgepole pine, ponderosa pine and western white pine in that all seven species are resinous softwood species in the scientific classification order Pinaceae, but larch does not share a common genus with any of these species. It appears to be most similar to douglas fir, engelmann spruce and white spruce in that the four species have small, sparse resin canals as opposed to the large numerous resin canals of the pines. See http://www.faculty.sfasu.edu/mcbroommatth/lectures/wood_science/lab_2_resin_canal_species.pdf. While the white spruce EF for formaldehyde is greater than that of douglas fir at high drying temperatures, the opposite is true at low drying temperatures. The douglas fir EF equation for formaldehyde is based upon seven tests while the white spruce EF equation is based upon two. All other HAP EF are greater for douglas fir at all drying temperatures. Under the circumstances, EPA Region 10 has decided to substitute the douglas fir formaldehyde EF equation. See the white spruce (appearing under engelmann spruce tab) and douglas fir HAP sheets for lab-scale test data and calculations.

In the absence of larch test data, douglas fir test data has been substituted. Larch is similar to douglas fir, engelmann spruce, white spruce, lodgepole pine, ponderosa pine and western white pine in that all seven species are resinous softwood species in the scientific classification order Pinaceae, but larch does not share a common genus with any of these species. It appears to be most similar to douglas fir, engelmann spruce and white spruce in that the four species have small, sparse resin canals as opposed to the large numerous resin canals of the pines. See http://www.faculty.sfasu.edu/mcbroommatth/lectures/wood_science/lab_2_resin_canal_species.pdf. Because the douglas fir EF is greater than that of white spruce (and EPA Region 10 is not aware of any VOC test data for engelmann spruce), the douglas fir EF has been substituted. See the douglas fir VOC sheet for lab-scale test data and calculations.

Larch (Douglas Fir Substitution) WPP1 VOC Emission Factor

WPP1 VOC (lb/mbf): $0.01460x - 1.77130$; where x is maximum drying temperature in °F

Hazardous Air Pollutant Emission Factors for Drying Lodgepole Pine Lumber

This sheet presents lab-scale test data and calculations used to create HAP EF for drying lodgepole pine lumber in an indirect steam-heated batch kiln. The EF are calculated by averaging test results. Lodgepole pine testing was performed while drying lumber at a relatively high maximum temperature of around 237°F. Because emissions increase with maximum drying temperature, employing an EF based upon testing at 237°F would overreport emissions when drying at maximum drying temperatures less than 237°F.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Lodgepole Pine HAP Emission Test Data by Drying Temperature¹

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)	Lumber Dimensions	Moisture Content ² (%) (Initial / Final)	Time to Final Moisture Content (hours)	HAP Sample Collection Technique	Reference

Volatile Organic Compound Emission Factors for Drying Lodgepole Pine Lumber

This sheet presents lab-scale EPA Reference Method 25A (RM25A) and speciated VOC test data and calculations used to create VOC EF for drying lodgepole pine lumber in an indirect steam-heated batch kiln. Although three RM25A VOC tests were performed while drying lodgepole pine, they were performed while drying lumber at a relatively high maximum temperature of around 238°F. Because emissions increase with maximum drying temperature, employing an EF based upon testing at 238°F would overreport emissions when drying at maximum drying temperatures less than 238°F.

RM25A has some limitations in that it misses some pollutant compounds (or portions thereof) that are VOC and known to exist and reports the results "as carbon" which only accounts for the carbon portion of each compound measured. The missed pollutant compounds (some HAP and some non-HAP) are accounted for through separate testing. RM25A test data is adjusted to fully account for two known pollutant compounds that are VOC using separate speciated test data and is reported "as propane" to better represent all of the unspciated VOC compounds. This technique is consistent with EPA's Interim VOC Measurement Protocol for the Wood Products Industry - July 2007 (WPP1 VOC).

More specifically, one VOC emission rate is calculated based upon underlying RM25A and speciated VOC test data as indicated above. Temperature-specific methanol and formaldehyde emission rates are calculated for each temperature at which RM25A testing was performed using temperature-dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. EPA Region 10 is not aware of any further speciated VOC test data. That portion of the (speciated) VOC compounds that are measured by the RM25A test method (based on known flame ionization detector response factors) is subtracted from the RM25A measured emission rate. The remaining "unspciated" RM25A emission rate is adjusted to represent propane rather than carbon and then added to the speciated VOC emission rate to provide the "total" temperature-specific VOC emission rate.

Note that reporting the unspciated VOC as propane (mass-to-carbon ratio of 1.22 and a response factor of 1) may underestimate the actual mass of VOC for certain wood species because VOC compounds like ethanol and acetic acid with higher mass-to-carbon ratios (1.92 and 2.5, respectively) and lower response factors (0.66 and 0.575, respectively) can be a significant portion of the total VOC. Based upon the mass-to-carbon ratios and response factors noted above, 1 lb/mbf ethanol is reported as 0.4194 lb/mbf propane and 1 lb/mbf acetic acid is reported as 0.2806 lb/mbf propane through the use of EPA Reference Method 25A unless compound-specific sampling and analysis is performed. The contribution of ethanol and acetic acid has been quantified through sampling and analysis for douglas fir and ponderosa pine. For douglas fir, ethanol's contribution over three tests was measured to be 0, 1.4 and 5.4 percent of WPP1 VOC, and acetic acid's contribution over the same three tests was measured to be 37, 20 and 13 percent of WPP1 VOC. For ponderosa pine, ethanol's contribution over one test was measured to be 32 percent of WPP1 VOC, and acetic acid's contribution over the same test was measured to be 6.4 percent. Without reliable lodgepole pine lumber drying test data for ethanol and acetic acid, EPA assumes propane adequately represents the mix of unspciated VOC.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Lodgepole Pine RM25A VOC Emission Test Data by Drying Temperature

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)	Lumber Dimensions	Moisture Content ¹ (%) (Initial/Final)	Time to Final Moisture Content (hours)	Method 25A Analyzer	Reference
236	1.17	2x4	59.1 / 15	16.01	JUM 3-200	3, 4, 12
238	0.87	2x4	56.9 / 15	16.01		
240	1.19	2x4	64.9 / 15	16.81		

¹ Dry basis. Moisture content = (weight of water / weight wood) x 100

Step Two: Calculate Lodgepole Pine VOC Emission Factor¹

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)
238	1.0767

¹ Three-run average.

Step Three: Adjust Ponderosa Pine VOC Emission Test Data to Account for Bias in Underlying Small-Scale Kiln to Represent Full-Scale Kiln Emissions¹

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)
238	0.8951

Adjusted OSU emission test data value = (OSU reported emission test data value) X (NCASI TB No. 845 study full-scale kiln value/NCASI TB No. 845 study OSU small-scale kiln value)

where: OSU reported emission test data value is the RM25A VOC as carbon emission rate "lb/mbf" documented in Step One (not highlighted in green)

NCASI study full-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in a full-scale indirect steam-heated batch lumber dry kiln

NCASI study OSU small-scale kiln value is the average RM25A VOC as carbon emission rate "lb/mbf" measured while drying southern yellow pine lumber in OSU's small-scale indirect steam-heated batch lumber dry kiln

The lumber dried in the OSU kiln was (a) extracted from the pool of lumber dried in the full-scale kiln and (b) dried according to the schedule employed by the full-scale kiln.

NCASI TB No. 845 - Emission Rate (lb/mbf)

RM25A VOC as carbon

Full-Scale Kiln 3.53333

OSU Kiln 4.25000

Step Four: Compile Lodgepole Pine Speciated HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing¹

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
238	0.0550	0.0030	no data	no data	no data

¹ See lodgepole pine HAP sheet for lab-scale test data and calculations.

Step Five: Compile Lodgepole Pine Speciated Non-HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A VOC Testing

Maximum Dry Bulb Temperature (°F)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)
238	no data	no data

Step Six: Convert Lodgepole Pine Speciated HAP Emission Factors to "as Carbon" and Total

Speciated Compound "X" expressed as carbon = (RF_x) X (SC_x) X [(MW_c) / (MW_x)] X [(#C_x) / (#C_c)]

where: RF_x represents the flame ionization detector (FID) response factor (RF) for speciated compound "X"

SC_x represents emissions of speciated compound "X" expressed as the entire mass of compound emitted

MW_c equals "12.0110" representing the molecular weight (MW) for carbon as carbon is becoming the "basis" for expressing mass of speciated compound "X"

MW_x represents the molecular weight for speciated compound "X"

#C_x represents the number of carbon atoms in speciated compound "X"

#C_c equals "1" as the single carbon atom is becoming the "basis" for expressing mass of speciated compound "X"

Maximum Dry Bulb Temperature	Methanol as Carbon	Formaldehyde as Carbon	Acetaldehyde as Carbon	Propionaldehyde as Carbon	Acrolein as Carbon	Ethanol as Carbon	Acetic Acid as Carbon	Speciated Compounds as Carbon

(°F)	(lb/mbf)	(lb/mbf)	(lb/mbf)	(lb/mbf)	(lb/mbf)	(lb/mbf)	(lb/mbf)	SUM	(lb/mbf)
238	0.0148	0	no data	no data	no data	no data	no data	⇒	0.0148

Element and Compound Information

Element / Compound	FID RF ¹	Molecular Weight (lb/lb-mol)	Formula	Number of Carbon Atoms	Number of Hydrogen Atoms	Atoms	Reference
Methanol	0.72	32.042	CH ₄ O	1	4	1	1
Formaldehyde	0	30.0262	CH ₂ O	1	2	1	16
Acetaldehyde	0.5	44.053	C ₂ H ₄ O	2	4	1	20
Propionaldehyde	0.66	58.0798	C ₃ H ₆ O	3	6	1	20
Acrolein	0.66	56.064	C ₃ H ₄ O	3	4	1	20
Ethanol	0.66	46.0688	C ₂ H ₆ O	2	6	1	1
Acetic Acid	0.575	60.0524	C ₂ H ₄ O ₂	2	4	2	1
Propane	1	44.0962	C ₃ H ₈	3	8	0	16
Carbon	-	12.0110	C	1	-	-	-
Hydrogen	-	1.0079	H	-	1	-	-
Oxygen	-	15.9994	O	-	-	1	-

¹ FID RF = volumetric concentration or "instrument display" / compound's actual known concentration. Numerator and denominator expressed on same basis (ie. carbon, propane, etc) and concentration in units of "ppm."

Step Seven: Subtract Speciated HAP and Non-HAP Compounds from Lodgepole Pine VOC Emission Factors and Convert Result to "as Propane"

$$\text{Method 25A VOC as propane without speciated compounds} = (\text{VOC}_C) \times (1/\text{RF}_{\text{C}_3\text{H}_8}) \times ((\text{MW}_{\text{C}_3\text{H}_8}) / (\text{MW}_C)) \times ((\#C_C) / (\#C_{\text{C}_3\text{H}_8}))$$

where: VOC_C represents Method 25A VOC as carbon without speciated compounds

RF_{C₃H₈} equals "1" and represents the FID RF for propane. All alkanes, including propane, have a RF of 1.

MW_{C₃H₈} equals "44.0962" and represents the molecular weight for propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

MW_C equals "12.0110" and represents the molecular weight for carbon

#C_C equals "1" as the single carbon atom was the "basis" for which Method 25A VOC test results were determined as illustrated in Step One of this spreadsheet

#C_{C₃H₈} equals "3" as three carbon atoms are present within propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

Note: The following portion from the equation immediately above, (1/RF_{C₃H₈}) X ((MW_{C₃H₈}) / (MW_C)) X ((#C_C) / (#C_{C₃H₈})), equals 1.2238 and can be referred to as the "propane mass conversion factor."

Step Eight: Calculate WPP1 VOC by Adding Speciated HAP and Non-HAP Compounds to Lodgepole Pine VOC Emission Factors "as Propane"

WPP1 VOC = Method 25A VOC as propane without speciated compounds + ∑ speciated compounds expressed as the entire mass of compound

Hazardous Air Pollutant Emission Factors for Drying Ponderosa Pine Lumber

This sheet presents lab-scale test data and calculations used to create HAP EF for drying ponderosa pine lumber in an indirect steam-heated batch kiln. The methanol and formaldehyde EF are temperature dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The acetaldehyde, propionaldehyde and acrolein EF are calculated by averaging test results.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Ponderosa Pine HAP Emission Test Data by Drying Temperature

Maximum Dry Bulb Temperature (°F)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)	Lumber Dimensions	Moisture Content ¹ (%) (Initial / Final)	Time to Final Moisture Content (hours)	HAP Sample Collection Technique	Reference

OSU Kiln	0.225	0.0210	0.065	0.003	0.009

Step Three: Calculate Ponderosa Pine HAP Emission Factors

Methanol ¹ (lb/mbf)	Formaldehyde ¹ (lb/mbf)	Acetaldehyde ² (lb/mbf)	Propionaldehyde ² (lb/mbf)	Acrolein ² (lb/mbf)
0.00137x - 0.18979	0.000074x - 0.010457	0.0340	0.0010	0.0026

¹ Best-fit linear equations with dependent variable maximum drying temperature entering the lumber

² Because acetaldehyde, propionaldehyde and acrolein emissions across different species are not consistently dependent upon maximum drying temperature, EF are calculated by averaging test results.

Volatle Organic Compound Emission Factors for Drying Ponderosa Pine Lumber

This sheet presents lab-scale EPA Reference Method 25A (RM25A) and speciated VOC test data and calculations used to create VOC EF for drying ponderosa pine lumber in an indirect steam-heated batch kiln. RM25A has some limitations in that it misses some pollutant compounds (or portions thereof) that are VOC and known to exist and reports the results "as carbon" which only accounts for the carbon portion of each compound measured. The missed pollutant compounds (some HAP and some non-HAP) are accounted for through separate testing. RM25A test data is adjusted to fully account for seven known pollutant compounds that are VOC using separate speciated test data and is reported "as propane" to better represent all of the unspciated VOC compounds. This technique is consistent with EPA's Interim VOC Measurement Protocol for the Wood Products Industry - July 2007 (WPP1 VOC) except that the RM25A results are adjusted to account for not only methanol and formaldehyde but also for acetaldehyde, propionaldehyde, acrolein, ethanol and acetic acid in this case.

More specifically, ten separate drying-temperature-specific VOC emission rates (upon which a best-fit linear equation will be established) are calculated based upon underlying RM25A and speciated VOC test data as indicated above. Temperature-specific methanol and formaldehyde emission rates are calculated for each temperature at which RM25A testing was performed using temperature-dependent best-fit linear equations. The temperature variable reflects the maximum temperature of the heated air entering the lumber. The temperature-independent acetaldehyde, propionaldehyde and acrolein emission rates reflect the average of all test results independent of the temperature of heated air entering the lumber. The ethanol and acetic acid emission rates reflect the results of a single test. EPA Region 10 is not aware of any further speciated VOC test data. That portion of the (speciated) VOC compounds that are measured by the RM25A test method (based on known flame ionization detector response factors) is subtracted from the RM25A measured emission rate. The remaining "unspciated" RM25A emission rate is adjusted to represent propane rather than carbon and then added to the speciated VOC emission rate to provide the "total" temperature-specific VOC emission rate. The resultant VOC EF is a 10-point best-fit linear equation with dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Test data generated through the use of the smaller of the two small-scale kilns at Oregon State University (OSU) has been adjusted to account for bias documented in NCASI's May 2002 Technical Bulletin No. 845 entitled, "A Comparative Study of VOC Emissions from Small-Scale and Full-Scale Lumber Kilns Drying Southern Pine." See last spreadsheet of this workbook for Stimson Lumber Company's October 18, 2019 letter to EPA Region 10 highlighting the bias.

Step One: Compile Ponderosa Pine RM25A VOC Emission Test Data by Drying Temperature¹

Maximum Dry Bulb Temperature (°F)	Method 25A VOC as Carbon (lb/mbf)	Lumber Dimensions	Moisture Content ² (%) (Initial/Final)	Time to Final Moisture Content (hours)	Method 25A Analyzer	Reference

¹ See ponderosa pine HAP sheet for lab-scale test data and calculations.

² Methanol EF = 0.00137x - 0.18979; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

³ Formaldehyde EF = 0.000074x - 0.010457; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber.

Step Four: Compile Ponderosa Pine Speciated Non-HAP Emission Test Data by Drying Temperature

Maximum Dry Bulb Temperature (°F)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)	Lumber Dimensions	Moisture Content ¹ (%) (Initial / Final)	Time to Final Moisture Content (hours)	VOC Sample Collection Technique	Reference
180	0.826	0.162	2x4	103.9 / 15	39.4	NCASI Method 105	Link to March 7, 2013 Hampton Affiliates - Randle Test Report

¹ Dry basis. Moisture content = (weight of water / weight wood) x 100

Step Five: Calculate Ponderosa Pine Speciated Non-HAP Emission Factors

Ethanol (lb/mbf)	Acetic Acid (lb/mbf)
0.826	0.162

Step Six: Calculate/Compile Ponderosa Pine Speciated Non-HAP Emission Factors at Maximum Drying Temperatures Observed during RM25A Testing

Maximum Dry Bulb Temperature (°F)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)
170	0.826	0.162
176		
180		
235		

Step Seven: Convert Ponderosa Pine Speciated HAP and Non-HAP Emission Factors to "as Carbon" and Total

Speciated Compound "X" expressed as carbon = (RF_x) X (SC_x) X [(MW_C) / (MW_x)] X [(#C_x) / (#C_C)]

where: RF_x represents the flame ionization detector (FID) response factor (RF) for speciated compound "X"

SC_x represents emissions of speciated compound "X" expressed as the entire mass of compound emitted

MW_C equals "12.0110" representing the molecular weight (MW) for carbon as carbon is becoming the "basis" for expressing mass of speciated compound "X"

MW_x represents the molecular weight for speciated compound "X"

#C_x represents the number of carbon atoms in speciated compound "X"

#C_C equals "1" as the single carbon atom is becoming the "basis" for expressing mass of speciated compound "X"

Maximum Dry Bulb Temperature (°F)	Methanol as Carbon (lb/mbf)	Formaldehyde as Carbon (lb/mbf)	Acetaldehyde as Carbon (lb/mbf)	Propionaldehyde as Carbon (lb/mbf)	Acrolein as Carbon (lb/mbf)	Ethanol as Carbon (lb/mbf)	Acetic Acid as Carbon (lb/mbf)
170	0.0116	0	0.0093	0.0004	0.0011	0.2843	0.0373
176	0.0139	0					
180	0.0153	0					
235	0.0357	0					

SUM →

Speciated Compounds as Carbon (lb/mbf)
0.3461
0.3487
0.3505
0.3749

Element and Compound Information

Element / Compound	FID RF ¹	Molecular Weight (lb/lb-mol)	Formula	Number of Carbon Atoms	Number of Hydrogen Atoms	Number of Oxygen Atoms	Reference
Methanol	0.72	32.042	CH ₄ O	1	4	1	1
Formaldehyde	0	30.0262	CH ₂ O	1	2	1	16
Acetaldehyde	0.5	44.053	C ₂ H ₄ O	2	4	1	20
Propionaldehyde	0.66	58.0798	C ₃ H ₆ O	3	6	1	20
Acrolein	0.66	56.064	C ₃ H ₄ O	3	4	1	20
Ethanol	0.66	46.0688	C ₂ H ₆ O	2	6	1	1
Acetic Acid	0.575	60.0524	C ₂ H ₄ O ₂	2	4	2	1
Propane	1	44.0962	C ₃ H ₈	3	8	0	16
Carbon	-	12.0110	C	1	-	-	-
Hydrogen	-	1.0079	H	-	1	-	-
Oxygen	-	15.9994	O	-	-	1	-

¹ FID RF = volumetric concentration or "instrument display" / compound's actual known concentration. Numerator and denominator expressed on same basis (ie. carbon, propane, etc) and concentration in units of "ppm."

Step Eight: Subtract Speciated HAP and Non-HAP Compounds from Ponderosa Pine VOC Emission Factors and Convert Result to "as Propane"

Maximum Dry Bulb Temperature (°F)	FROM STEP TWO	MINUS	FROM STEP SEVEN	EQUALS	Method 25A VOC as Carbon without Speciated Compounds (lb/mbf)	Propane Mass Conversion Factor	Method 25A VOC as Propane without Speciated Compounds (lb/mbf)
	Method 25A VOC as Carbon (lb/mbf)		Speciated Compounds as Carbon (lb/mbf)				
170	1.3219		0.3461		0.9758		1.1942
170	1.7950		0.3461		1.4489		1.7732
170	1.9250		0.3461		1.5789		1.9323
176	1.0725		0.3487		0.7238		0.8857
176	1.2803		0.3487		0.9316		1.1401
176	1.1639		0.3487		0.8152		0.9976
176	1.0808		0.3487		0.7321		0.8959
180	1.2304		0.3505		0.8799		1.0769
180	1.4300		0.3505		1.0795		1.3210
235	2.4941		0.3749		2.1192	X 1.2238 =	2.5934

Method 25A VOC as propane without speciated compounds = (VOC_C) X (1/RF_{C3H8}) X [(MW_{C3H8}) / (MW_C)] X [(#C_C) / (#C_{C3H8})]

where: VOC_C represents Method 25A VOC as carbon without speciated compounds

RF_{C3H8} equals "1" and represents the FID RF for propane. All alkanes, including propane, have a RF of 1.

MW_{C3H8} equals "44.0962" and represents the molecular weight for propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

MW_C equals "12.0110" and represents the molecular weight for carbon

#C_C equals "1" as the single carbon atom was the "basis" for which Method 25A VOC test results were determined as illustrated in Step One of this spreadsheet

#C_{C3H8} equals "3" as three carbon atoms are present within propane; the compound that is the "basis" for expressing mass of VOC per WPP1 VOC

Note: The following portion from the equation immediately above, (1/RF_{C3H8}) X [(MW_{C3H8}) / (MW_C)] X [(#C_C) / (#C_{C3H8})], equals 1.2238 and can be referred to as the "propane mass conversion factor."

Step Nine: Calculate WPP1 VOC by Adding Speciated HAP and Non-HAP Compounds to Ponderosa Pine VOC Emission Factors "as Propane"

WPP1 VOC = Method 25A VOC as propane without speciated compounds + ∑ speciated compounds expressed as the entire mass of compound

Maximum Dry Bulb Temperature (°F)	FROM STEP EIGHT	FROM STEP THREE					FROM STEP SIX		WPP1 VOC (lb/mbf)
	Method 25A VOC as Propane without Speciated Compounds (lb/mbf)	Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)	Ethanol (lb/mbf)	Acetic Acid (lb/mbf)	
170	1.1942	0.0431	0.0021						2.2650
170	1.7732	0.0431	0.0021						2.8440
170	1.9323	0.0431	0.0021						3.0031
176	0.8857	0.0513	0.0026						1.9652
176	1.1401	0.0513	0.0026						2.2195
176	0.9976	0.0513	0.0026	0.0340	0.0010	0.0026	0.826	0.162	2.0771
176	0.8959	0.0513	0.0026						1.9753
180	1.0769	0.0568	0.0029						2.1621
180	1.3210	0.0568	0.0029						2.4063
235	2.5934	0.1322	0.0069						3.7581

Step Ten: Generate Ponderosa Pine Best-Fit Linear Equation with Dependent Variable Maximum Drying Temperature to Model WPP1 VOC Emissions

WPP1 VOC (lb/mbf): 0.02083x - 1.30029 ; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumber

Hazardous Air Pollutant Emission Factors for Drying Western White Pine Lumber

This sheet presents the HAP EF for drying western white pine lumber. EPA Region 10 is not aware of any HAP emission testing of western white pine. When actual test data is not available, data for a similar species is substituted as noted. When there are more than one similar species, the highest of the EF for the similar species is substituted.

Given the limited western white pine test data, ponderosa pine test data has been substituted. Western white pine is similar to ponderosa pine and lodgepole pine in that all three species are resinous softwood species in the scientific classification genus Pinus. EPA Region 10 is aware of three Lodgepole Pine test runs for methanol and formaldehyde and none for acetaldehyde, propionaldehyde and acrolein. Five ponderosa pine test runs were conducted for methanol and formaldehyde and three for acetaldehyde, propionaldehyde and acrolein. While the lodgepole pine runs were conducted at about the same maximum drying temperature, the ponderosa pine runs were distributed across a wide maximum drying temperature range. Based upon the available test data, ponderosa pine is higher-emitting than lodgepole pine for methanol and formaldehyde. See the ponderosa pine and lodgepole pine HAP sheets for lab-scale test data and calculations.

Western White Pine (Ponderosa Pine Substitution) HAP Emission Factors

Methanol (lb/mbf)	Formaldehyde (lb/mbf)	Acetaldehyde (lb/mbf)	Propionaldehyde (lb/mbf)	Acrolein (lb/mbf)
0.00137x - 0.18979	0.000074x - 0.010457	0.0340	0.0010	0.0026

Volatile Organic Compound Emission Factors for Drying Western White Pine Lumber

This sheet presents the VOC EF for drying western white pine lumber. EPA Region 10 is aware of one test being conducted while drying western white pine lumber, and it was conducted at 170°F. Because VOC emissions increase with maximum drying temperature, employing an EF based upon testing at 170°F would underreport emissions when drying at maximum drying temperatures greater than 170°F. A temperature of 170°F is not a particularly high drying temperature. When little or no actual test data is available, data for a similar species is substituted as noted. When there are more than one similar species, the highest of the EF for the similar species is substituted.

Given the limited western white pine test data, ponderosa pine test data has been substituted. Western white pine is similar to ponderosa pine and lodgepole pine in that all three species are resinous softwood species in the scientific classification genus *Pinus*. EPA Region 10 is aware of three lodgepole pine test runs and eight ponderosa pine test runs. While the lodgepole pine runs were conducted at about the same maximum drying temperature, the ponderosa pine runs were distributed across a wide maximum drying temperature range. Based upon the available test data, ponderosa pine is higher-emitting than lodgepole pine. See the ponderosa pine and lodgepole pine HAP and VOC sheets for lab-scale test data and calculations.

Western White Pine (Ponderosa Pine Substitution) WPP1 VOC Emission Factor

WPP1 VOC (lb/mbf): $0.02083x - 1.30029$; where dependent variable "x" equal to the maximum drying temperature of heated air entering the lumt

Reference No. 1

(Undated) J.U.M. Flame Ionization Detector Response Factor Technical Information presented at <http://www.jum-aerosol.com/images/E-Fakt-02.pdf>

Notes

Methanol response factor (RF) of 0.72 equals average of three response factors 0.69, 0.68 and 0.79 for J.U.M. models 3-200 and VE-7. These two models were exclusively employed to determine Method 25A VOC in the testing EPA Region 10 is relying upon to support VOC emission factor derivation.

An alternative RF of 0.65 from Appendix 3 to EPA's Interim VOC Measurement Protocol for the Wood Products Industry - July 2007 at <http://www.epa.gov/ttn/emc/prelim/otm26.pdf> could have been employed instead.

Employing RF of 0.72 (as opposed to 0.65) generates lower VOC emission factors (EF). A higher RF means that the EPA Method 25A flame ionization detector (FID) measures more of the compound. With the methanol EF having already been determined through speciated sampling and analysis, assuming the FID measures a greater portion of the methanol leaves less of the Method 25A measurement to be accounted for as unspciated VOC.

National Council of the Paper Industry for Air and Stream Improvement, Inc. Technical Bulletin No. 718. July 1, 1996. A Small-Scale Kiln Study on Method 25A Measurements of Volatile Organic Compound Emissions from Lumber Drying.

Notes

To convert Method 25A VOC from "lb C/ODT" to "lb C/mbf," the following calculations were performed:

White Fir – Runs 15 and 16.

$$(0.85 \text{ lb/ODT}) \times (0.57 \text{ lb/mbf}) / (0.77 \text{ lb/ODT}) = 0.63 \text{ lb/mbf}$$

$$(0.68 \text{ lb/ODT}) \times (0.57 \text{ lb/mbf}) / (0.77 \text{ lb/ODT}) = 0.50 \text{ lb/mbf}$$

See pages 14 and 15 of the reference document.

Western Red Cedar – Runs 10 and 11.

$$(0.12 \text{ lb/ODT}) \times (0.12 \text{ lb/mbf}) / (0.15 \text{ lb/ODT}) = 0.096 \text{ lb/mbf}$$

$$(0.17 \text{ lb/ODT}) \times (0.12 \text{ lb/mbf}) / (0.15 \text{ lb/ODT}) = 0.136 \text{ lb/mbf}$$

See pages 14 and 15 of the reference document.

Douglas fir – Runs 1 and 3.

$$(1.00 \text{ lb/ODT}) \times (0.81 \text{ lb/mbf}) / (0.86 \text{ lb/ODT}) = 0.942$$

$$(0.71 \text{ lb/ODT}) \times (0.81 \text{ lb/mbf}) / (0.86 \text{ lb/ODT}) = 0.669$$

See pages 12 and 15 of the reference document.

Ponderosa Pine – Runs 5 and 6.

$$(1.92 \text{ lb/ODT}) \times (1.86 \text{ lb/mbf}) / (1.99 \text{ lb/ODT}) = 1.795 \text{ lb/mbf}$$

$$(2.06 \text{ lb/ODT}) \times (1.86 \text{ lb/mbf}) / (1.99 \text{ lb/ODT}) = 1.925 \text{ lb/mbf}$$

See pages 14 and 15 of the reference document.

The moisture content of wood was originally reported on a wet basis. It has been corrected to be on a dry basis using the following equation:
(moisture content on dry basis) = (moisture content on wet basis) / [1 – (moisture content on wet basis)]

Notes

Acetaldehyde and propionaldehyde RF appear in Table C-1 of Appendix C. The values are estimates based upon dividing the compound's effective carbon numbers (ECN) by the number of carbon atoms in the compound. See Attachment 2 to Appendix C.

Acrolein RF is also an estimate based upon dividing the compound's ECN by the number of carbon atoms in the compound. In this case, the RF estimate does not appear in Table C-1 of Appendix C. The value is calculated as described above pursuant to Attachment 2 to Appendix C.

RF = (ECN) / (number of carbon atoms in compound)

where ECN = 2 given the aliphatic carbon contribution of CH₂CHCHO (see Table 2.1 to Appendix C) and the number of carbon atoms in acrolein = 3.
RF = 2/3 or 0.66

RE: Proposed Kiln Emissions Factors for Stimson, Plummer Title V Renewal

Dear Mr. Hardesty:

Stimson wishes to thank EPA for the time and effort that has gone into the technical analysis needed for renewal of the Plummer facility's Title V permit. We are appreciative of the opportunity to review the proposed emissions factors for the permit analysis.

We have looked over the proposed kiln emission factors, as well as the work done by the Washington Southwest Clean Air Agency (SWCAA) and have the following comments. In general, we agree that the approach is an improvement over previous efforts and, in particular, the use of a regression equation for the formaldehyde and methanol emissions is superior to having a single cut point.

The issue of concern is the reliance upon small lab-scale kilns to derive the emissions factors. For a number of reasons, these kilns are not representative of operations at full-scale production kilns. Based upon work that we present below, this seems to be particularly true of the OSU kiln used by Dr. Milota, which serves as the primary source of HAP emission factors for western species. The unfortunate fact is that there is very little data comparing the emissions from a small lab kiln to those of a production kiln - in fact, we are only aware of NCASI Technical Bulletin 845 from 2002. However, based upon that study, we find the following differential in measured emissions:

From NCASI Technical Bulletin 845:

Pollutant	FSK	OSU	OSU:FSK
VOC	3.5	4.3	1.23
Formaldehyde	0.016	0.021	1.31
Methanol	0.21	0.23	1.10
Acetaldehyde	0.039	0.065	1.67
Acrolein	0.006	0.009	1.50
Propionaldehyde	0.001	0.003	3.00

FSK = Full Scale Kiln

OSU = Oregon State University lab scale kiln

We note that the OSU kiln yields a consistently higher bias in the emissions - by an average of 64%. Neither the Mississippi State nor the Horizon Engineering kilns demonstrated this consistent high bias so we do not believe it is simply a matter of the difficulty in fully characterizing the production kiln. In the technical bulletin NCASI staff come to the conclusion that "...VOC emissions measured at a small-scale kiln can reasonably approximate those from a full-scale kiln..." However, this conclusion is based upon

the full sample set from multiple small scale kilns. Indeed, if we include the Phase II MSU kiln results in the analysis the average results are much closer. Unfortunately, virtually all of the western species data is from the OSU kiln, so there is a high bias. What significant differences in the operation of the OSU kiln can account for this consistently higher bias?

Unidirectional flow: Unlike full scale production kilns, the OSU kiln features unidirectional airflow. Production kilns have reversible fans that allow bidirectional air flow. The OSU design results in uneven drying that would be unacceptable in a commercial environment.

Hotter wood: The smaller charge size in the OSU kiln results in less volume of wood to absorb the thermal energy of the surrounding air. This is further compounded by the shorter linear distance the air has to travel over in the lab kiln. The result is anticipated to be hotter wood than equivalent kiln temperatures would yield in a full scale production kiln. Thus, we would expect the dry bulb temperature to be less indicative of the actual wood temperature in a full scale kiln than in the lab kilns. This is borne out by the faster drying time in the OSU kiln.

Increased airflow: Table 8.3 of NCASI Technical Bulletin 845 illustrates the dramatically enhanced airflow through the lab kiln relative to a full scale production kiln:

Table 8.3. Phase II Total Volume of Kiln Exhaust Gas per MBF

Test Charge	FSK	MSU	OSU
	scfm x 10 ³ per MBF		
Direct Fired Drying Schedule			
DF1	18.80	8.36	9.19
DF2	18.10	8.72	9.04
DF3	17.30	8.74	9.11
DF4	18.10	7.67	6.61
DF5	17.50	7.73	9.75
DF6	17.00	8.90	9.85
Average	17.80	8.33	8.97
Steam-Heated Drying Schedule			
INDF1	2.69	8.62	8.99
INDF2	3.98	9.96	7.37
INDF3	3.75	9.95	8.20
INDF5	3.44	10.90	7.25
INDF6	3.38	6.68	7.56
INDF7	3.71	7.29	8.48
Average	3.49	8.90	8.07

Note that for steam heated kilns the airflow of the OSU kiln averages over 200% greater on a per unit of lumber basis. This is likely to increase emissions by enhancing pollutant removal.

Of course, the best case scenario would be to have comprehensive production kiln test results, but this would be very expensive and difficult to acquire. And, in any event, it is not currently available. Thus, the straight-forward approach to adapting the lab kiln results is to simply adjust the lab emissions by a correction factor. Absent additional data, the NCASI Technical Bulletin is what we have available to do this. Applying such a correction factor yields the factors attached.

Thus, Stimson proposes revised emission factors for the facility. We note, however, that this accepts that temperature is a valid parameter for correlation with emissions. At this time, Stimson has not looked closely at whether moisture contents might be a useful in this regard. Less data is likely to be available for a moisture approach and it would likely suffer the same issues with scaling of lab kiln results. Further, we have largely accepted EPA's sample selection and analysis due to time constraints. Stimson may look at this in more detail as discussions continue.

We will be providing an analysis of boiler emission factors shortly.

Sincerely,

A handwritten signature in black ink, appearing to read "Steven Petrin". The signature is written in a cursive style with a large, looping initial "S".

STEVEN PETRIN
Environmental Manager
