## Appendix H

### Relative Accuracy Assessment

To assess the performance of the composite emissions factor uncertainty ratios, the calculated emissions factor target statistics were compared to the hypothetical population values for the target statistic for each emissions factor evaluated during the study. The following equation was used to calculate relative accuracy:

$$RA = (EF_{target\ statistic} - HP_{target\ statistic})/HP_{target\ statistic} \times 100$$

where:

$RA$	=	Relative accuracy
$EF_{target\ statistic}$	=	Target population value of the emissions distribution, hereafter referred to as the target statistic (e.g., 95th percentile), in units of the AP-42 emissions factor
$EF$	=	Emissions factor, as presented in AP-42, in units of the AP-42 emissions factor
$HP_{target\ statistic}$	=	Actual value of the hypothetical population for the target statistic of interest for the emissions factor (e.g., 95 <sup>th</sup> percentile of the hypothetical population distribution)

and:

$$EF_{target\ statistic} = EF * EF_{uncertainty\ ratio}$$

where:

$$EF_{uncertainty\ ratio} = \text{Composite uncertainty ratio for pollutant and target statistic of interest}$$

An example calculation for the HAP, HCl–Refuse Combustion, Mass Burn, follows.

Given:

- a) Published AP-42 emissions factor = 0.198 lb/ton
- b) Number of tests published emissions factor is based upon,  $n = 14$
- c) 95<sup>th</sup> percentile of the hypothetical population,  $HP_{95th} = 0.67$  lb/ton
- d) Composite default emissions factor uncertainty ratio for HAPS, where the target statistic is the 95<sup>th</sup> percentile and  $10 \leq n < 25$ , = 4.3

Then:

$$\begin{aligned} EF_{target\ statistic} &= EF * EF_{uncertainty\ ratio} \\ EF_{95th\ percentile} &= 0.198\ \text{lb/ton} * 4.3 \\ &= 0.85\ \text{lb/ton} \end{aligned}$$

and:

$$\begin{aligned} RA &= (EF_{target\ statistic} - HP_{target\ statistic})/HP_{target\ statistic} * 100 \\ &= (0.85 - 0.67)/0.67 * 100 \\ &= 27\% \end{aligned}$$

Similarly for the target statistic of the 90<sup>th</sup> percentile for the same pollutant:

Given:

- a) Published AP-42 emissions factor = 0.198 lb/ton
- b) Number of tests published emissions factor is based upon,  $n = 14$
- c) 90<sup>th</sup> percentile of the hypothetical population,  $HP_{90th} = 0.49$  lb/ton
- d) Composite default emissions factor uncertainty ratio for HAPS, where the target statistic is the 90<sup>th</sup> percentile and  $10 \leq n < 25$ , = 2.7

Then:

$$\begin{aligned} EF_{\text{target statistic}} &= EF * EF_{\text{uncertainty ratio}} \\ EF_{90\text{th percentile}} &= 0.198 \text{ lb/ton} * 2.7 \\ &= 0.53 \text{ lb/ton} \end{aligned}$$

and:

$$\begin{aligned} RA &= (EF_{\text{target statistic}} - HP_{\text{target statistic}})/HP_{\text{target statistic}} * 100 \\ &= (0.53 - 0.49)/0.49 * 100 \\ &= 10 \% \end{aligned}$$

In these two examples, the emissions factor target statistic calculated using the composite emissions factor uncertainty ratio overestimates the 90<sup>th</sup> and 95<sup>th</sup> percentiles by 10 and 27 percent, respectively.

Table H-1 presents the relative accuracy calculations for each emissions factor evaluated during this study for the 10<sup>th</sup>, 25<sup>th</sup>, median, 75<sup>th</sup>, 90<sup>th</sup>, and 95<sup>th</sup> target statistics. The average, median, minimum, and maximum relative accuracy values are presented for each pollutant type for which composite uncertainty ratios were developed, i.e., HAPS; PM-condensable; PM-filterable, controlled; PM-filterable, uncontrolled; and gaseous criteria pollutants.

With the exception of PM-condensable, in general the composite uncertainty ratios overestimate the target statistics. In particular, the composite uncertainty ratios overestimate the percentiles below the median; i.e., the 10<sup>th</sup> and 25<sup>th</sup> percentiles.

Table H-1. Relative Accuracy Calculations.
